SIR ALMROTH WRIGHT'S LECTURE ON THE TREATMENT OF WOUNDS IN WAR.

BY SIR W. WATSON CHEYNE, BART., C.B., F.R.S.,
PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

IN this short note in reference to Sir Almroth Wright's recent lecture on the treatment of wounds in war I do not propose to criticise his paper; indeed, I am in agreement with a good many of his statements, especially with those on the use of antiseptics in septic wounds. In speaking of the treatment of septic wounds Sir Almroth Wright objects to the use of antiseptics, and in the present state of our knowledge I believe that he is quite right. This is a point which I have taught for years and on which I laid special stress in my paper at the Medical Society last November. Indeed, I would go further than Sir Almroth Wright appears to do in objecting to the practice of syringing out these wounds with antiseptic lotions. I dislike to see septic wounds washed out with antiseptics. That procedure cannot possibly disinfect the wound nor in any way diminish the sepsis even temporarily except by the mechanical removal of the pus, which can be done much more safely by the use of isotonic solutions, and not only so, but the antiseptic may seriously interfere with the antibacterial action of the tissues especially if it is at all a strong solution used under the idea that it will act as a bactericide.

Free drainage and irrigation, referred to by Sir Almroth Wright, are of course well-known and long-established methods of treating septic wounds, and are, in my opinion, the best methods of dealing with them. The only new practical point in Sir Almroth Wright's suggestions, a point which, however, he had made previously, is the use of a strong solution of salt with the view of leading to increased flow of lymph. Curiously enough, it is stated that this acts by osmosis, but that must surely be a slip of the pen. Colloids such as lymph dialyse very slowly or not at all, and practically the only result of placing a strong solution of salt outside a blood-vessel would be the exit of the water and salts of the blood. Any increased flow of lymph which may arise from the introduction of a hypertonic salt solution into a wound will be the result of irritation, and the question then arises whether salt is the best irritant, or whether, indeed, it is wise to use an irritant at all. I must confess that my inclination is against the employment of irritants because I doubt very much whether the lymph does contain all, or indeed the most important, antibacterial substances of the body. My own view is that these substances reside in the tissues themselves to a much greater degree than in the blood and lymph, and the application of an irritant may seriously interfere with the natural processes. However that may be, I shall watch with great interest Sir Almroth Wright's attempts to eradicate sepsis from wounds by what he terms "physiological methods."

The reason why I am writing this note is, however, to emphasise the point on which I am particularly insistent—viz., that while Sir Almroth Wright's studies concern wounds as they reach him at the base hospitals, already in a highly septic state and in a stage in which antiseptics as ordinarily employed are of no avail, there is a preceding period, which he does not come across, in which the septic process has not yet taken root in the wound, and in which it may be eradicated by the proper use of antiseptics. It is on this period that my researches are concentrated, and at this stage the use of antiseptics presents to my mind the only possible chance of success. Our work and Sir Almroth Wright's are in no way antagonistic. He takes matters up at a stage where our suggestions are possibly no longer of any special value or where these suggestions have not been followed or have failed to accomplish their object. But what a change in the whole aspect of military surgery if our plans should succeed! What a saving of suffering and of life! And reports are beginning to come in which show that such success is not improbable. Surely this is the most important point in the treatment of these wounds, and I do not think that we can too often call the attention of the profession to this most important, though short, period in the history of these cases. This is the time for the employment of antiseptics, and I am convinced that if suitable antiseptics are chosen, and if they are thoroughly and scientifically applied, a very considerable proportion of the cases will escape the dangers and the troubles of a septic wound.

It is being constantly said that there is something peculiar and special in wounds in war as compared with those which occur in civilian practice. In my opinion this is not so; it is only a question of degree and not of kind. I have been very much surprised to read in the daily papers accounts of the wonderful discoveries which were being made at the front with regard to the bacteriology of these wounds, of the anaerobic bacteria, the coliform bacilli, the streptococci, and so on. But the same bacteriological flora is common enough in civil injuries, especially in those soiled with earth, and are quite familiar to those of us who have made a study of these matters. Nor are the bacteria in injuries in civil practice confined to the exterior of the wound, as Sir Almroth Wright seems to imply. The whole wound becomes infected just as happens in the wounds which he meets with at the military base hospitals, and septic compound fractures are often just as serious in civil as in military practice. From reading his remarks one would think that all compound fractures in civil practice ran an aseptic course. Alas! far from it. Sir Almroth Wright, when he comes back to this country, will find ample opportunities for continuing his search for a physiological method of treating septic wounds.

The difference between the military and the civilian compound fractures is one of degree and not of kind. In the civilian cases the injury is usually more limited than in those inflicted on the field of battle; there are seldom the long channels in the tissues, difficult of access, in the former which occur in the latter, but there is the same blood clot and the same torn and bulging muscles, rendering the channel irregular, in the one as in the other. And though the infection may be carried in further in the military than in the civilian cases, this does not, I think, mean so much as one might at first sight suppose. The bullets or the pieces of shell soon part with the septic material which they carry in with them, as shown by the frequency with which these bodies become encapsuled. This was an observation made long ago by John Hunter, who built up a theory that if a bullet were in the depth of the tissues the latter did not resent its presence or make any attempt to remove it, while if it remained near the surface they underwent suppuration with the view of extruding it.

I hope that these two stages in the history of wounds in war, the one before sepsis has become established and the other after it has taken root, will be clearly differentiated in the minds of those who have to deal with them, and that, because the latter cannot be disinfected by our present means, surgeons will not therefore relax their attempts to eradicate the septic elements in the former or early stage while there is still time to do so. It is a terrible attitude to take up that these wounds must necessarily become septic and that it is useless to make any attempt to prevent this occurrence.

TREATMENT OF THE WOUNDED ON BOARD H.M.S. "TIGER" DURING THE NAVAL ACTION OF JAN. 24TH.

BY J. C. KELLY, M.D., B.A. DUB.,
SURGEON R.N.

THERE were two medical distributing stations, one aft and the other forward. I was stationed at the after one, which was situated directly beneath the quarter deck and immediately forward of X turret. We had a plentiful supply of water from two large fresh-water tanks, while hot water could be supplied from a steam geyser. There were two cases of "emergency surgical dressings," one big medicine chest, and a set of drawers containing tourniquets, bandages, strapping, instruments, and all the drugs and medicines most likely to be required. In case of the electric light failing, light could be obtained from six oil lamps, which were fixed in convenient places; besides an operating table we had a small stand for basins and another for instruments.

My first-aid party consisted of about nine persons altogether, including three of the sick-berth staff, the remainder consisting of gun-room and ward-room stewards, cooks, &c. The forward distributing station was quite accessible from the after one by means of the ammunition passage. My senior medical officer and the other surgeon were stationed here, as well as a similar first-aid party consisting of officers' stewards, cooks, &c. Like the after one, the forward distributing station was fitted with hot and cold water, operating table, cases of dressings, &c., and in addition there was an X ray apparatus; the tubes, however, were broken during action owing to the concussion caused by our fire.

It was arranged that after the action the party stationed aft should search for wounded in Q and X turrets and along the port 6-inch battery, and that the party stationed forward should search A and B turrets and the starboard 6-inch battery. We soon had everything rigged up, dressings and lotions out, and the operating table ready in case it would be wanted, and then my party came forward of the bulkhead next the distributing station into the ammunition passage, and there we remained during the entire action.

At 8 A.M. we sighted the enemy off our port bow, and at 9.2 A.M. we fired our first shot, and from that on until the "secure" sounded the firing continued. The time passed quickly, and after the first half hour when the excitement of hearing our own guns fire in anger had passed off, my first-aid party spent the time endeavouring to find out what was happening, and later on when they heard we had been hit they discussed the chances of our going back to Devonport and getting some leave while the ship was being repaired. One or two started reading papers, but they did not do so for long as things became too "hot." Each time we were hit the shell caused a terrific crash, shook the ship, then one could hear any quantity of loose débris and splinters falling.

At about 11.20 our first patient was brought to us, a boy (Case 11) suffering from burns about the face and a sprained ankle. We soon treated him and put him in one of the officers' cabins close by. Very soon after the chief gunlayer (Case 5) walked from Q turret, in spite of his receiving a compound fracture of the right fibula; he was badly burned about the face and left eye, and had a badly lacerated wound in the left hand, fracturing the first metacarpal bone. As we were under a very heavy fire at this time, and with so little armoured protection, I did not care to treat him in the after station, so I sent him to the forward distributing station where his wounds could be more efficiently dealt with.

When the action was over we searched for wounded. I went to Q turret. In the gun house we discovered two men dead, and in the working chamber below we found an A.B. (Case 6). He was suffering from considerable pain in his side, so we put him in a Neil Robertson stretcher, and after hoisting him up into the gun house through a trap-door we eventually got him out of the turret, and from there carried him down to the after distributing station. We strapped his left side, gave him a $\frac{1}{4}$ gr. of morphia (as he was suffering from a certain amount of shock), and then put him in one of the adjoining officers' cabins. The only other case treated in the after station was another A.B. (Case 8). I then went to the forward distributing station where the remainder of the wounded had been brought. All the injuries of the patients that had been brought here were caused by a shell which exploded in the intelligence office, which was situated under the signal distributing office and gun-control tower where these patients were stationed. This shell also accounted for 8 deaths.

In the afternoon we brought all the patients up from the distributing stations to the sick bay, where their wounds were thoroughly cleansed and again dressed. We arrived back at our base on the following Tuesday morning (Jan. 26th). The three wounded officers were transferred to the hospital yacht, *Sheelah*, and the men to the Naval Sick Quarters, South Queensferry.

CASE 1. *Burns of the face and fracture of left ulna.*—A lieutenant. This officer came to the forward distributing station during action, suffering from burns of the face and scorching of the scalp, the result of a shell explosion beneath the gun-control tower where he was stationed. His hair was badly scorched, but the scalp did not appear to be burnt. The burns about the face were mostly of the first degree. There was a certain amount of shock present, so that morphia, gr. $\frac{1}{4}$, was given hypodermically the same night. The burns were dressed with picric acid. There was also a small fracture of the left ulna situated about its middle, consisting of a small triangular piece of bone detached from the posterior border of the ulna. On Jan. 26th he was transferred to the hospital yacht *Sheelah* for further treatment.

CASE 2. *Multiple injuries.*—A sub-lieutenant. This officer came to the forward distributing station during the action suffering from multiple injuries received, the result of a shell explosion near the gun-control tower where he was stationed. There was a deep scalp wound on the left side of the vertex about 2 in. long; both membranæ tympanorum were ruptured, causing bleeding from both ears; there was a wound perforating the lower lip, the lower incisor teeth were knocked backwards, and the left angle of the jaw was fractured. On the lower and inner side of the left knee there was a flap of skin and superficial fascia separated up to its base (about the level of the internal semilunar cartilage), the base being about 3 in. and the length of the flap 2 in. The wound did not involve the knee-joint. On the right thigh there was a burn of the second degree. In the afternoon he was brought to the sick bay, where his injuries were dressed under an anæsthetic. The wound on the inner side of the knee was swabbed with pure carbolic, then sutured. His scalp wound was thoroughly cleansed, then sutured. The other wounds were also carefully cleansed and dressed. The wound perforating the lip was sutured, the suture not involving the mucous membrane. The ears were lightly plugged with gauze. Eight minims of antistreptococcic serum were injected hypodermically the same evening; the usual reaction followed; also morphia, gr. ¼. He was transferred to the hospital yacht *Sheelah* on Jan. 26th for further treatment.

Case 3. *Abdominal injury.*—A midshipman. This officer was brought to the forward distributing station from the gun-control tower where the pointer of the director was driven into his abdomen just below the xiphisternum, the result of a shell explosion. He also received an incised wound in the right leg and burns of the first and second degree on both legs and genitals. He suffered considerable pain in the region of his abdominal wound, but apparently it did not perforate the abdominal wall. It was treated with iodine solution and dressed with gauze. The wound in the right leg was a small incised one situated at the back of the internal malleolus where the flexor tendons had been partially severed; this wound also received a simple dressing. The burns were treated with picric acid dressings. He was given ¼ gr. of morphia that night hypodermically, also ♏ 8 of antistreptococcic serum. The following morning he stated he had not had a good night. Temperature 104° F.; pulse 108. There were marked tenderness and rigidity in the region of the wound, but none in the lower part of the abdomen. His general appearance was good and there was never any vomiting. He was given another hypodermic injection of morphia, gr. ¼, that night (Monday). The following morning (Tuesday) he stated he felt much better. The temperature had fallen to 99° and the pulse to 99. There was still considerable amount of tenderness and rigidity in the region of the wound. He was transferred to the hospital yacht *Sheelah* for further treatment.

Case 4. *Fracture of the left femur.*—This patient, a stoker messenger, received the above injury during the action. While descending from the signal distributing office down the escape to the deck below, the shock caused by firing the 13·5 guns caused him to fall and fracture his left femur. He was brought to the forward distributing station, where a fracture in the middle of the left femur was easily diagnosed. He suffered considerably from shock, so morphia, gr. ¼, was given hypodermically and a long Liston splint applied. After the action he was put to bed in the sick bay. As he still suffered from shock, morphia, gr. ¼, was given hypodermically that evening and again the following Monday. He was transferred to the Naval Hospital, Queensferry, on Jan. 26th for further treatment.

Case 5 *Lacerated wound of the hand; compound fracture of first metacarpal and right fibula.*—Chief petty officer. This patient walked to the after distributing station during the action suffering from the above injuries the result of a shell explosion. On examination there was a compound fracture of his right fibula just above the external malleolus. There was a bad laceration of the left hand, fracturing (compound) the first metacarpal bone. There was also a smaller wound in the right hand, as well as burns about the face and left eye from cordite. The wounds were carefully dressed and the fractured fibula was put up in splints. Morphia, gr. ¼, was injected that night and again the following night. Treated with ♏ 8 of antistreptococcic serum and had well-marked reaction afterwards. He was transferred to the Naval Hospital, Queensferry, for further treatment on Jan. 26th.

Case 6. *Fractured rib.*—This patient (an A.B.) was brought to the after distributing station from Q turret suffering from severe pain in the left side in the region of the eleventh rib. He received his injury during the action, and it was due to a shell explosion which caused his left side to fall against a supporting piece. On examination there was severe pain on pressure over the lower ribs on the left side; the left side of the chest was strapped. He suffered considerably from shock, so morphia, gr. ¼, was given hypodermically. His abdomen was very rigid, and though at first he complained of no pain, later on he did, and at 8 P.M. he passed 4 oz. of bright red blood per urethram. There was no evidence of urinary infiltration into his scrotum or elsewhere, and a catheter was not passed. His temperature and pulse remained normal. No specially tender spot could be detected in his abdomen, although he kept it rigid. The following day the blood completely disappeared from his urine; his temperature and pulse remained normal, and he felt better, although there was still some rigidity present. He was discharged on Jan. 26th to the Naval Hospital at South Queensferry for further treatment.

Case 7. *Burns of the face and head.*—A stoker. This patient was brought to the forward distributing station from the signal distributing office during the action suffering from burns of the face and head. The eyes were not affected. Picric acid dressings were applied, and morphia, gr. ¼, was given hypodermically the same night. On Jan. 26th he was transferred to the Naval Hospital, South Queensferry, for further treatment.

Case 8. *Wounds of the feet.*—This man (an A.B.) came to the after distributing station after the action suffering from wounds in both feet due to splinters from a shell explosion. On the left foot there was a small but deep cut from which he pulled out a piece of shrapnel about 1½ in. long; there was a certain amount of oozing from the wound. There was also another smaller wound on the dorsum of the right foot. Simple dressings were applied. He was transferred to the Naval Hospital, South Queensferry, on Jan. 26th for further treatment.

Case 9. *Fractured clavicle.*—A stoker. This patient came to the forward distributing station during the action, after being blown back and falling down the fore escape owing to a shell explosion. He received a fracture beween the outer and middle thirds of his clavicle (right). The fracture was put up by the Sayres method. He was transferred Jan. 26th to the Naval Hospital, Queensferry, for further treatment.

Case 10. *Burns of the left side of face and neck.*—This boy was brought from the fore 6 inch control during the action suffering from burns of the first and second degree of the left side of the face and neck. Picric acid dressings were applied. He was transferred to the Naval Hospital on Jan. 26th for further treatment.

Case 11. *Burns of the face; sprain of the right ankle.*—This boy was brought to the after distributing station during the action, suffering from slight burns of the face and scorching of the scalp, as well as a sprained right ankle, the result of a shell explosion near the signal distributing office, where he was stationed. There was some shock present, so morphia, gr. ¼, was given hypodermically. Picric acid dressings were applied to the burns, and lead lotion to the sprained ankle. He was transferred to the Naval Hospital, South Queensferry, on Jan. 26th, for further treatment.

I regret at not being able to obtain more details as to the progress the patients made after we discharged them to hospital. They all steadily improved, and some of them, I believe, have returned to duty already. The case of the midshipman (Case 3) gave us some cause for anxiety, as we thought exploratory operation desirable to find out if the parietal peritoneum was perforated; but as his symptoms were not urgent, and considering the very septic condition of the ship, we came to the conclusion such a procedure was too risky. When he was removed to the *Sheelah* no operation was considered necessary. His condition progressed favourably, and he is now convalescent. A fracture of the sternum was subsequently discovered.

None of the patients received any active treatment except the chief petty officer (Case 5), who was operated on the hand for suture of tendons, and the sub-lieutenant (Case 2), who had an operation for septic parotitis resulting from the fracture of the left angle of the jaw. Later on he developed a cellulitis in his left forearm, caused by a piece of cordite which entered at the wrist and fetched up in the middle of the forearm; the piece of cordite was afterwards removed. I believe that the stoker (Case 4) had his fractured femur plated, but I was unable to find out definitely.

EPIDEMIC CEREBRO-SPINAL MENINGITIS.[1]

BY FREDERICK E. BATTEN, M.D. CANTAB., F.R.C.P. LOND.,

PHYSICIAN TO HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, ETC.

MAY I thank the Harveian Society for the honour they have done me in asking me through their secretary to open the discussion on this most important subject? It is one which has always interested me, for in my connexion with the Children's Hospital, Great Ormond-street, it has been possible to study the disease in its endemic form and to compare the features of the endemic with the epidemic type of the disease. Your excellent secretary has wisely allocated certain portions of this subject to other speakers specially skilled in their various departments, and my part will be to give a general review of the subject, leaving it to subsequent speakers to fill in the numerous gaps. I shall more especially deal with the clinical features, diagnosis, and treatment of the disease, leaving it to others to deal with the bacteriology, vaccine-therapy, &c.

Epidemiology of the Disease.

It must be recognised that cerebro-spinal meningitis is no new disease either in its endemic or epidemic form. During the last century epidemics have occurred on the continent, in America, and in this country. The last epidemic in this country was in 1907–08, when it occurred in Belfast and Glasgow. It may be said to be an endemic disease in Norway, and if one studies the excellent monograph on the subject published by Looft one sees that it not only is constantly found in that country, but varies in its incidence not only from year to year but also according to the season of the year. It must be recognised that cerebro-spinal meningitis due to the meningococcus is constantly present in London. It is an endemic disease but has an epidemic period in the spring of each year, the greatest number of cases occurring during the months of February, March, and April, falling off during May and June—only a few cases occurring during the last six months of the year.

It is interesting to compare the course of this disease with that of poliomyelitis, an endemic disease having a seasonal variation showing a curve which begins to rise in June, reaches its maximum in August, falls away to a low level in November. Cerebro-spinal meningitis as an endemic disease affects chiefly children, and especially infants below the age of one year. In the year 1907 epidemic cerebro-spinal meningitis was made a notifiable disease in the county of London and permanently so in 1912. It is interesting to note that in this year also poliomyelitis was made a notifiable disease.

The disease is spread by the transference of the meningococcus from individual to individual. As Professor Andrewes rightly points out, "the disease does not spread as a meningitis; what is spread is the meningococcus; the meningitis is an accident, which happens only in a certain proportion of those invaded by the meningococcus."

Misleading Names under which the Disease is Known.

The names under which this disease is known are somewhat misleading. Epidemic cerebro-spinal meningitis presupposes that the spinal membranes are invariably affected, which is not always the case, for cases of acute meningococcal septicæmia occur in which death supervenes before the meninges are affected. "Spotted fever" suggests that the disease is accompanied by a rash—a symptom which is by no means constantly present. Epidemic cerebro-spinal fever might serve, but even such a name suggests that the spinal membranes must be affected.

Meningococcal fever or septicæmia might be suggested, but that would not certainly solve the difficulty, and would raise bacteriological difficulties which might be harder to deal with than the clinical inconsistencies. Let us stick to the name epidemic cerebro-spinal meningitis, recognising that just as the pneumococcus may at times give rise to infection in different parts of the body—thorax, peritoneum, joints, membranes of the brain—so the meningococcus may in like manner fall on different structures, but seems to have a preference for the membranes of the brain.

Experimental Work.

In 1905 Flexner produced cerebro-spinal meningitis in the monkey by injecting subdurally virulent cultures of the meningococcus. The infective inflammation produced resembled the human infection closely, except that it was often more severe. The inoculation caused severe illness in a few hours and death in from 18 to 24 hours. At the height of the infection a blood invasion occurred. The rapidly fatal instances resembled the fulminating cases among human beings, the other the human cases of average severity. A monkey was immunised and the serum obtained therefrom injected directly into the spinal canal of infected monkeys with favourable results; if injected into the blood and subcutaneous tissues the animals succumb. An immune serum prepared in a horse by alternate injections of dead and living cultures was shown to have similar properties to the serum produced in monkeys. By the use of this serum the mortality, which in untreated cases is about 80 to 90 per cent., fell to 18 per cent. for those treated within the first three days of illness, to 27 per cent. between the fourth and seventh day of illness, and to 36 per cent. when treated after the seventh day. It is important to remember that the mortality among cases occurring towards the end of an epidemic is considerably lower than that at the beginning.

Clinical Features.

Shortly stated, epidemic cerebro-spinal meningitis may be said to be an acute epidemic disease starting with fever, vertigo, severe headache, and vomiting. Delirium is often present, and the patient complains of intense pain in the back and neck and often of a sore-throat. A *rash* may be present over the body, either as a mottling of the skin or as raised erythematous areas with a small central vesicle into which hæmorrhage may occur. The rash is usually distributed over the periphery of the limbs, and is, except for its distribution, like a measles rash. In the acute form of the disease the patient has the appearance of a profound toxæmia. The soft palate is injected, the fauces swollen and red and covered over with mucous secretion which gives them a grey appearance. It is interesting to note that though there is this intense injection of the fauces the gland at the angle of the jaw may show little enlargement.

---

[1] A paper read before the Harveian Society of London on April 22nd, 1915.

The patient lies with the legs flexed and the neck held rigid and resents movement. If an attempt be made to extend the legs it is found that they cannot be extended beyond a right angle to the thigh. The patient may be acutely conscious of his condition, and may from time to time become delirious and violent, at other times he may be completely comatose. In an acute case the disease may run its whole course in a few hours, headache, delirium, coma rapidly succeeding one another so that death occurs within 24 hours. In some cases there may be profound septicæmia without any sign of meningitis, and in such cases on lumbar puncture the cerebro-spinal fluid may be found normal. These are cases of acute meningococcal septicæmia.

Now by the side of such an acute disease as is above presented one has the case of a patient with fever, headache, and vomiting, but without any definite signs on examination. In spite of the temperature being high, there is little or no acceleration of the pulse, respiration is quiet, after a few days the temperature falls, the headache becomes less, and the patient is convalescent. What is the nature of such a case? It may be designated "influenza," and few would deny that it may be due to the influenza bacillus. If a lumbar puncture is performed the cerebro-spinal fluid may be found to be turbid and contain meningococci, but the case gets well whether lumbar puncture is done or not, and few practitioners would wish to subject their patients to the inconvenience of a lumbar puncture for a slight febrile attack, and yet such an attack may be the onset of an acute meningitis.

In infants and young children, again, the symptoms and course of the disease often make it most difficult to diagnose. In severe cases with a rash, profound coma, and rigidity of the limbs there is no difficulty. When, however, a rise of temperature is the only sign of illness the difficulty is considerable, and diagnosis can only be made by lumbar puncture and examination of the cerebro-spinal fluid. It must not be thought that such cases are exceptional, they are probably far from rare and pass undiagnosed. In infants blindness is a frequent concomitant of the disease, whilst in adults deafness is more frequent.

As the disease passes into a chronic stage retraction of the head and neck may occur, and in infants marked opisthotonos is a striking feature. In the endemic form occurring annually in London there is a mortality of about 50 per cent., 35 per cent. are left with some mental defect, hemiplegia, diplegia, hydrocephalus, or blindness, whilst only 15 per cent. recover completely. In the epidemic form the mortality varies from 90 per cent. in the earlier period of an epidemic to 30 to 50 per cent. towards the end of the period. These figures are based on the occurrence of the disease before the introduction of serum treatment which has profoundly modified the mortality.

It is known that there are several strains of meningococcus which vary in their infectivity, and that the endemic strain is commonly less virulent than the epidemic—on the other hand, as severe cases do occur with the one strain as with the other.

Diagnosis.

In some cases the symptoms are so distinct that diagnosis is perfectly easy, the headache, vomiting, rash, fever, rigid neck, and flexed limbs giving a clinical picture which is unmistakable. Symptoms similar to the above may be present in other forms of meningitis or in poliomyelitis, and there is only one method of making the diagnosis certain, and that is by lumbar puncture and examination of the cerebro-spinal fluid. Now lumbar puncture is perfectly simple if performed with an instrument suitable to the age of the patient, the patient in the right position and in the right manner. If properly carried out it gives rise to but little pain, and in many cases it is quite unnecessary to give an anæsthetic.

It is impossible here to go into the technique of a lumbar puncture, but failure to reach the canal or obtain the fluid rarely occurs when the puncture is rightly performed. It is advisable that the patient should be in a recumbent position, lying on the right side with the legs flexed and the back bent, and that a fine needle with a stilette be used. If a large needle is used it is much more painful and in young children will not pass the space between the laminæ. Some lumbar puncture needles that I have seen are unnecessarily large. It is important to avoid touching the bone if possible, it always gives rise to more pain, and is likely to cause bleeding into the needle which may block it or contaminate the cerebro-spinal fluid and spoil the cytological examination.

The cerebro-spinal fluid spurts out under pressure. Sometimes it is so thick that it will not flow through a fine needle, but comes out readily under gentle aspiration. All degrees of turbidity are met with, from a slightly opaque to a thin creamy fluid. It is said that the fluid from some cases may be perfectly clear and yet contain meningococci. I have never come across such a case, but they have been recorded by Netter and others. It is recognised that the cerebro-spinal fluid from a case of meningococcal septicæmia may be perfectly clear, and the patient may die from the disease before the cerebro-spinal system is affected. The albumin in the fluid is increased from 0·02 to 0·2 or even to 1 per cent.; the cells are mostly polymorphonuclear in character and the meningococcus can be seen within and outside the cell. The normal sugar reaction of the fluid is absent.

As the case progresses and improvement takes place the fluid becomes clearer, the meningococci less frequent, the cells less numerous and changed in character, so that in the later stages of the disease the greater proportion of the cells are lymphocytic.

Treatment.

Having made the diagnosis treatment should be simple if we accept the experimental and statistical evidence produced by Flexner with regard to the use of serum. The mortality which in untreated cases amounts to 70 to 80 per cent. is brought down to from 25 to 27 per cent. Unfortunately there are various strains of the meningococci, and the serum obtained from a horse immunised against certain strains of meningococci is not potent against all strains. It is, of course, possible always to add one more strain to a horse already immunised, for I believe that such a horse receives about every 14 days a further injection of meningococci, so that the serum of the horse may be made polyvalent to any number of strains. Flexner showed that subcutaneous and intravenous injection of the serum had no effect in diminishing the mortality in cases of meningitis.

Methods of Treatment.

The following methods of treatment will be discussed:—(1) Lumbar puncture; (2) intrathecal injection of serum; (3) treatment with soamin; and (4) vaccine treatment.

1. *Lumbar puncture.*—This alone is often of considerable value in treating cases of cerebro-spinal meningitis. It frequently relieves many of the acute symptoms. It may be repeated on several days in succession with advantage; it is also of value in estimating the progress made by the meningitis. Combined with this, irrigation of the spinal canal with normal saline solution may be used. This injection can be done either with the syringe or by gravitation method with a funnel and rubber tube attached to the lumbar puncture needle. It is important to watch the pulse whilst the fluid is being run into the canal and to avoid any increase in the cerebro-spinal pressure.

2. *Intrathecal injection of serum.*—There are several points to be considered in the intrathecal injection of serum. First, what serum should be used. There are various sera on the market prepared by Flexner, Lister Institute, Mulford's, Burroughs and Wellcome, Parke Davis, &c. Flexner's (now prepared by the Department of Health, New York) I have used most frequently. Some of the others I have used, but it is most difficult to appraise the value of the serum, for it may not be antitoxic to the special strain of meningococcus with which one is dealing.

Injection of the serum.—Lumbar puncture is performed and the spinal fluid is allowed to flow out. The quantity that flows away must depend on a variety of circumstances—the age and size of the patient, the amount of pressure, but at least 20 to 30 c.c. should be obtained. Sometimes it flows out so readily that 4 to 5 ounces are obtained.

Sophian insists on the value of watching the blood pressure whilst the fluid is flowing away, and if there is a fall of more than a few millimetres stop the flow and begin to inject the serum. The injection of the serum does not, however, tend to raise the blood pressure, but tends to make it fall still further, so that from the time of the lumbar puncture to the completion of the injection of the serum there may be a drop of 20 to 30 mm. of mercury. Sophian is entirely guided by the blood pressure as to the quantity of cerebro-spinal fluid removed and the quantity of serum introduced—and any pressure in injecting the serum produces a rapid fall of blood pressure. The amount of serum introduced must vary according to the age of the patient. In young children 10 c.c. can usually be introduced, whereas in adults 20 to 30 c.c. or more can be introduced.

Method of introduction.—The usual method of introduction is by a syringe, and having always used this method I am of opinion that the pressure exerted can easily be regulated. On the other hand, Sophian insists on the advantage of giving the serum by the gravitation method and controlling its administration by the blood pressure. He says: "My ordinary procedure in an adult case, beginning with an average blood pressure of 110 mm. of mercury, is to stop the further withdrawal of fluid if there is a moderate drop in blood pressure, for example, 10 mm. of mercury; in children 5 mm. If there is no change in the blood pressure the fluid may be allowed to flow away till the normal pressure is reached, roughly estimated by counting the drops of fluid as they flow from the needle. One drop of fluid every 3–5 seconds corresponding to a normal pressure."

The serum having been carefully warmed to the body temperature is now injected. The blood pressure drops and continues dropping steadily as the larger quantity of serum is injected. After there has been an initial drop of 20–30 mm. of mercury the blood pressure begins to drop relatively much faster if more serum is injected. Thus if 15 c.c. of serum cause a drop of 20 mm. of mercury in the blood pressure, injecting only a few more c.c. of serum may cause a sudden drop of 40 more millimetres, making a total drop of 60 mm. The gravitation method of administering serum is excellent, but in practice it is not easy to carry out nor to control by blood-pressure observation, and the syringe method is to me more convenient. The quantity of serum injected must be regulated by the condition of the patient; if it flow in easily 20 c.c. is an average dose. After the serum has been injected the patient should be tilted so that the head is lower than the buttocks, in order to allow of the serum, which is of greater specific gravity, gravitating towards the brain.

How many and how often should injections be given?—As soon as the diagnosis has been made the first injection should be given, and this should be repeated every 24 hours and the fluid examined on each occasion. The important indication for the continuation or discontinuation of injection is the number of organisms present in the fluid. At first they are numerous, intra- and extra-cellular; later they become intracellular and finally disappear. As a rule, four to six injections are required to bring about the result, and this is the number which Flexner advises. The opacity of the fluid cannot always be taken as a guide; as a rule it becomes less turbid, and a fluid which rapidly becomes clear is an indication of good prognostic value.

It is, I think, a mistake to go on with frequent injections of serum after the acute stage of the disease has subsided. Lumbar puncture by itself will often relieve the symptoms, and it is advisable to do this from time to time both for this purpose and also to see the condition of the cerebro-spinal fluid.

3. *Use of soamin.*—Soamin was introduced in the treatment of trypanosomiasis about 1907, and about this time was used in the treatment of syphilis. Dr. George Low used it with success in the treatment of cerebro-spinal meningitis in Africa, and has advocated its use for the disease in this country. It is administered in 1 to 3 grain doses dissolved in water and injected intramuscularly on alternate days. For the treatment of acute meningococcal septicæmia it would seem a rational method of treatment, but it is difficult to see how it can have an effect on a meningitis. The greatest objection to its use is, however, its toxic effect in producing optic atrophy and blindness. Not a few cases of such blindness were produced by the use of the drug when it was given for syphilis in 1908 and 1909.

It is sometimes argued that any remedy must be used in such a severe disease as cerebro-spinal meningitis, but recovery with loss of sight must, I fear, be regarded as a greater disaster than death. It is stated that there is no case on record where optic atrophy has been caused by less than 60 grains and that this is then a safe total amount to be given. Considering what liability there is for the optic nerve to be affected by the disease itself I should personally feel disinclined to use a drug which tends to produce optic atrophy. If it is desired to use an arsenic preparation I would suggest salvarsan or neosalvarsan. Both preparations have had a long trial and do not appear to produce optic atrophy.

4. *Vaccines.*—The discussion on the use of vaccines in the treatment of the disease has been assigned to Dr. Colebrook, and I will not encroach on his sphere of action. I hope, however, he will make quite clear the possible value of vaccines in the prevention as distinct from the treatment of the disease.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THE PSYCHOLOGY OF TRAUMATIC AMBLYOPIA FOLLOWING THE EXPLOSION OF SHELLS.

By HUGH S. PEMBERTON, M.B., CH.B. LIVERP.,
LIEUTENANT, R.A.M.C.

THE paper by Mr. J. H. Parsons in THE LANCET of April 3rd on the above subject has reminded me of a case under my care which presented several features of psychological interest. The facts are as follows.

Sergeant ——, belonging to a battery of field artillery under my medical charge, was working his gun under rather heavy shell fire on March 14th. His gun was No. 1. A direct hit was made on No. 2 gun with high-explosive shell, killing three men. I saw Sergeant —— shortly afterwards, and although naturally excited he appeared otherwise normal. He went on working his gun until dawn the next day, when he collapsed and was found lying across one of the disembowelled corpses. In all he had been at work for about 12 hours continuously, during which time the battery had fired between four and five hundred rounds. I saw him again a few hours later; he was conscious but very feeble, and obviously much shaken. There was considerable amblyopia and distinct contraction of the fields of vision (rough test); no change in colour vision. The sense of taste was much blunted; he could barely distinguish between salt and powdered quinine tablets laid on the tongue. The sense of smell was practically absent, but this was not of much importance, as he stated that his smelling powers were at all times small. Hearing was naturally much affected, but not more so than that of several other men in the same battery; no tympanic fractures were discernible. There were no changes of cutaneous sensation in the face, arms, or trunk, but both thighs, from about the apex of Scarpa's triangle to the knee, showed curious alterations. There was partial anæsthesia—that is to say, a normally painful pin-prick was felt as a tactile sensation, while touching the skin lightly with cotton-wool was not felt at all. The patient merely complained of "numbness" in these areas. The motor changes were not striking; he naturally showed great fatigue in practically every muscle; the eyelids were half-closed, but there was no nystagmus. On the other hand, he walked slowly with a distinctly spastic gait; the knee-jerks were brisk. Other reflexes appeared normal; the plantar reflex was of the flexor type. I sent him back to the wagon lines for a week where, while the sensory changes gradually disappeared, symptoms of mental distress seemed to increase. He still walked feebly and spastically, and reverted continually to the sight of the dead men at the next gun, one of whom was a friend of his. I finally sent him into hospital and he is now, I believe, in England.

There are several obvious factors in the production of such signs and symptoms. 1. Excitement during a prolonged and somewhat critical attack. 2. Over-stimulation of eyes and ears. The flashes of night firing are very brilliant, while many batteries close together and all firing rapidly invariably produce temporary deafness among the gunners. 3. Some natural fear from close hostile bursts. 4. Disgust at the sight of the killed, two of whom were decapitated and one disembowelled. 5. Great physical and mental fatigue from continuous laying of the gun during 12 hours.

But why these factors, which must have been operative to some degree at least in all those near, should produce those results in this particular man I leave it to others to attempt an explanation.

On Active Service.

NOTE ON A CASE OF CEREBRO-SPINAL MENINGITIS:

THE TENACITY OF THE MENINGOCOCCUS.

By HENRY J. ALFORD, M.D. LOND.,
MEDICAL OFFICER OF HEALTH OF TAUNTON.

THE following case may be of interest in showing the length of time that the meningococcus may be found in the naso-pharynx after apparent recovery from the disease.

A case of cerebro-spinal meningitis was notified to me on March 2nd, 1915, on the morning of which the patient died, after an illness of five days. He was a boy, aged 9 years. On making inquires into the case I found that his elder brother had returned from Deal (on his discharge from the army) on Feb. 13th. He complained of feeling ill, with pains in his head and limbs, and he went to bed, sleeping in the same bed as his younger brother already mentioned. In about a week he felt quite well and returned to his work in this town. On March 31st I took a swab from his naso-pharynx and sent it immediately to the County Bacteriological Laboratory at Weston-super-Mare, and on April 4th I received a certificate from Dr. W. G. Savage stating, "Meningococcus present."

The case is interesting as showing that although the germ will only live a few hours on the swab, it may do so for at least two months in the naso-pharynx

Taunton.

A "FLY-DANGER" EXHIBITION.—There will shortly be opened at the Zoological Gardens, Regent's Park, London, N.W., an exhibition for the purpose of demonstrating to the public the best ways of combating the danger which arises from the disease-carrying habits of the house-fly. Traps of all kinds will be shown, and the preventive measures to be taken where it is necessary to collect manure heaps for garden and horticultural purposes indicated.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

Leukæmia.

A MEETING of this section was held on April 27th, Dr. A. E. GARROD, Vice-President, being in the chair.

Dr. A. J. HALL read notes of a case presenting symptoms of Lymphatic Leukæmia of acute onset terminating in complete recovery. The patient, a man aged 26 years, consulted his medical attendant in March, 1911, on account of swelling of the glands on the right side of the neck. He stated that he had noticed this coming on for a few days previously, but as it had given him no pain he did not seek advice earlier. During the next few days the swelling gradually increased and became slightly painful. He also felt shivery and out of sorts towards the late afternoons so that he went to bed early. During the last few nights he had been hot and sweated. At this time he did not complain of any sore-throat, nor could any cause be found for the glandular enlargement. Slight albuminuria was present, otherwise there was nothing abnormal. When seen by Dr. Hall six days later there was a large mass of glands in the right side of the neck extending from the clavicle to the edge of the jaw. Individual glands could be distinctly felt, fairly soft, but not discrete. They were painless and not tender on palpation. Besides this mass, solitary enlarged glands could be felt on both sides of the neck, both axillæ, and both groins. They were all firm and painless. The spleen was felt about three-quarters of an inch below the costal margin. He did not look anæmic. There was no sore-throat; his teeth were in good condition. There were no hæmorrhages. A blood examination showed: Hæmoglobin, 96 per cent. (Haldane); red corpuscles, 5,400,000; leucocytes, 32,000; lymphocytes, 96 per cent.; and polymorphonuclears, 4 per cent. No eosinophiles were seen, and there were no evident changes in the red cells. He had some pain in the glandular mass. His temperature was 101° F. in the evening. A provisional diagnosis of acute lymphatic leukæmia was made, and he was put on to liquor arsenicalis. After two days the glands were smaller and the patient complained for the first time of sore-throat on the right side. Later, vomiting occurred. A differential count was as follows: Large lymphocytes, 85·2 per cent.; small lymphocytes, 4·4 per cent.; and polymorphonuclears, 10·4 per cent. No eosinophiles were seen in counting 300 cells, nor were there changes in the red cells. The right tonsil became more painful and was covered with an exudate. The spleen extended lower in the abdomen. After this the improvement was steady and continuous week by week. In July the glands were only just palpable, and the spleen could hardly be felt. In August he was able to go shooting. From that time to the present he had remained in excellent health. Dr. Hall remarked that at the time of the acute onset the diagnosis of acute lymphæmia was provisionally made. The absence of severe anæmia, great prostration, and any tendency to hæmorrhage, together with the rapid and complete recovery, which had remained uninterrupted for four years, suggested that such provisional diagnosis was incorrect and that the case belonged to the category of lymphocytosis associated with cervical and general adenitis, to which attention had been more recently drawn. The existence of such cases should make our prognosis somewhat guarded in atypical cases suggesting acute lymphæmia.

Dr. HALL also narrated some cases of Myelogenic Leukæmia. 1. A case of chronic myelæmia treated by X rays in which, after a severe exacerbation, complete subjective recovery took place enabling the patient, a man aged 34, to perform his full work as electrician in a colliery for nearly three years. After this another severe exacerbation occurred lasting for three months, in which the liver became enlarged, with ascites; choked discs occurred on both sides with impaired vision and some hæmorrhages. With further X ray treatment all these symptoms disappeared and he had a further period of five months with complete subjective recovery and was able to continue full work. A third acute exacerbation followed ending in death about five months later. Particular stress was laid upon the long duration of the patient's first improvement, and the complete, though short, subjective recovery after the second exacerbation, when his leucocyte count was never below 300,000 and sometimes more than double that, and the spleen and liver were much enlarged. 2. Chronic myelæmia treated by X rays, with complete restoration to working health for about six months. During this time the leucocytes dropped to normal and remained so; the spleen from being extremely large was only just palpable. The patient died after a few days' acute illness which was called "pneumonia." 3. A chronic myelæmia in a woman, in whom the very large spleen had become completely dislocated so as to rest on the floor of the pelvis and form a large median tumour rising up into the abdomen and reaching above the navel. In the absence of a blood count the tumour had been diagnosed as pelvic in origin, and an exploratory laparotomy performed. Dr. Hall also spoke of a case of acute leukæmia associated with very severe and persistent pains in the bones.

Dr. F. PARKES WEBER read a short paper on an instance of Long Quiescence of Leukæmia. The patient, then aged 63, sought hospital advice in March, 1909,[1] for what she described as "bearing-down pains," "as if she were going to have a child." These pains seemed to come on when she became fatigued from walking, &c. Nothing abnormal was detected by gynæcological examination, but the spleen was found to be greatly enlarged, extending downwards decidedly beyond the anterior superior iliac spine. The liver could not be felt. The inguinal lymphatic glands were moderately enlarged on both sides, the axillary glands (on both sides) could only just be felt, and the cervical glands were apparently not enlarged at all. From March 16th to May 27th, 1909, the patient was in the German Hospital for treatment by atoxyl injections and radium applications (Dr. N. S. Finzi). The spleen distinctly decreased in size under the treatment, and the lymphatic glands in the groins became scarcely larger than they are in some healthy individuals. On Dec. 6th, 1909, the spleen did not quite reach the level of the anterior superior iliac spine. The following table shows the results of blood examinations up to the end of the year 1909:—

—	March 4, 1909.	March 29, 1909 (before radium treatment).	May 26, 1909 (after radium treatment).	Dec. 6, 1909.
Red cells per cubic millimetre of blood	4,100,000	4,176,000	3,800,000	5,740,000
Hæmoglobin per cent... ...	80	—	75	82
White cells per cubic millimetre of blood	57,000	43,200	12,000	47,120
Differential Count of White Cells per cent.				
Lymphocytes...	94·0	99·0	84·0	89·4
Neutrophile polymorphonuclears	0·8	0·5	14·0	10·0
Large hyalines	2·4	—	—	—
Intermediates...	2·8	—	—	—
Eosinophiles	0	0·5	2·0	0·2
Basophiles	0	—	—	0·4

The differential count on March 4th was kindly made by Dr. A. E. Boycott. Both eosinophiles and mast-cells were found, though none were present amongst the cells counted. The red cells appeared normal. No nucleated red cells were ever noted. Dr. Weber was able to examine the patient again on Dec. 4th, 1911, when she complained of rheumatic-like pains in her feet, but looked well. The inguinal glands were moderately enlarged on both sides, and the spleen could be felt extending down to below the anterior superior iliac spine. Blood examination (Dr. G. Dorner): Hæmoglobin, 70 per cent.; red cells, 5,380,000 per cubic millimetre of blood; white cells, 95,600. The differential count of white cells gave: Polymorphonuclear neutrophiles, 3·2 per cent.; lymphocytes, 96·6 per cent.; eosinophiles, 0·2 per cent. The erythrocytes appeared normal and no nucleated red cells were seen. In March, 1914, owing to the kindness of Dr. Garrod and his house physician, Dr. A. Geoffrey Evans, Dr. Weber examined the patient again while she was temporarily in St. Bartholomew's Hospital. She looked much the same as before, and complained of a little giddiness. A medical man, who had chanced to notice the enlarged spleen, had sent her to the hospital. The blood count showed: Hæmoglobin, 77 per cent.; red cells, 5,160,000 per cubic millimetre; white cells, 123,800. A differential count of the white cells showed that 96·5 per cent. were lymphocytes. Dr. Weber said that looking back on this case it appeared doubtful whether the symptoms which from time to time induced the patient to seek medical advice had any causal connexion with her chronic lymphocytic leukæmia, although in 1909 a real improvement was perhaps associated with the reduction in the size of the spleen by the radium and atoxyl therapy. In chronic lymphocytic leukæmia extreme enlargement of the spleen, as in this case, was an unusual feature, and perhaps the absence of anæmia had some prognostic importance. Might not this absence of anæmia be taken as showing that the red bone-marrow was not overwhelmed by the leukæmic disease, and that (in spite of the leukæmia) it remained able to maintain its normal erythropoietic activity, which was so essential to the well-being of the whole organism? It was quite conceivable that cases similar to the present one occurred in which the total number of white cells was much less than in it. The possibility of such a case being one of so-called "Banti's disease" (an example of permanently or temporarily "compensated" Banti's disease, without any considerable anæmia) might arise, but he believed that in all cases of chronic "Banti's disease," as well as in practically all cases of chronic splenomegaly, apart from the leukæmias, the tendency was towards a leucopenic blood count rather than towards an excess in the number of white cells. A condition of chronic splenomegaly combined with a numerical excess of white cells should always arouse a suspicion of the case being one of chronic leukæmia (in a more or less quiescent state).

---

[1] See F. P. Weber, Case of Chronic Lymphocytic Leukæmia without Anæmia, Transactions of the Medical Society of London, 1910, vol. xxxiii., p. 364.

Sir William Osler, who had seen Dr. Hall's case, said that it presented the clinical features of acute leukæmia, and the examination of the blood corresponded. He could not remember having seen a case with a lymphocyte count above 90 per cent. The only characteristic feature absent from the symptoms of Dr. Hall's case was purpura.

Dr. James Galloway said that he had had many opportunities of seeing the effects of treatment by means of X rays. The most striking result had occurred in the first case he had had treated in this way. It was one of myelæmia, the patient being extremely ill. The amount of improvement was wonderful and the patient lived for five years. Ultimately all the hæmopoietic processes seemed to cease and all the blood cells diminished. He had discovered no means of determining which cases were likely to be benefited by X ray treatment and which made worse. He also could remember a case in which mental symptoms developed resembling those of acute alcoholism.

Dr. W. Ironside Bruce spoke of the methods which he employed while treating such cases with X rays. He used a felt filter, for without a filter skin changes were sure to follow. The same reduction of the white cells occurred with the filter as without it. He preferred large infrequent doses rather than small continuous ones, and awaited the result of each dose. He made a practice of keeping the number of white cells as nearly as possible at 40,000; below that number they often dropped suddenly. He had not found that exposing the ends of the long bones, either alone or together with exposure of the spleen, was more beneficial than exposure of the spleen alone to the action of the rays. Speaking of the results of this form of treatment, he said that an effect was usually noticeable in the blood after two or three weeks. Improvement occurred in the patient's condition even in the absence of a fall in the leucocyte count. He did not think that the treatment influenced the ultimate prognosis, but the temporary improvement was very encouraging.

Dr. Parkes Weber was of opinion that no case of leukæmia had ever been cured. He took the view that Dr. Hall's case was not one of acute leukæmia but of lymphocytosis due to infection. The nature of the infection in such cases was unknown.

Dr. Hall, replying to the discussion, commented on the absence of any reference to benzol treatment, and stated that in the only case he had tried it the result had been disappointing. There was a slight diminution of leucocytes for a short time after first giving it, but this was not maintained.

SECTION OF DERMATOLOGY.

Exhibition of Cases and Specimens.

A meeting of this section was held on April 15th, Dr. J. J. Pringle, the President, being in the chair.

Dr. G. Pernet showed a Rodent Ulcer of three years' duration, in a man aged 26, and commented on the early age at which it had commenced.—The President, Sir Malcolm Morris, and Dr. J. H. Sequeira referred to similar cases seen at a less advanced age.

Dr. Pernet also brought forward a young man who exhibited extensive picric acid staining of the skin and hair due to his work, which was that of filling high-explosive shells.—Dr. S. E. Dore, Sir M. Morris, and Dr. A. M. H. Gray referred to the discolouration of the urine sometimes caused by the absorption of picric acid in the treatment of ringworm, burns, and other skin conditions, but which generally was unaccompanied by constitutional symptoms, but Dr. H. W. Barber recorded one case in which toxic symptoms occurred in a child.

Dr. Graham Little exhibited an Ulcer on the Foot due to several closely repeated X ray applications for a wart on the sole which had been administered by a layman. He asked for suggestions as to prognosis and treatment.—A general discussion ensued as to the value of X rays in the treatment of warts, in which the President, Dr. W. K. Sibley, Dr. H. G. Adamson, Dr. Dore, Dr. Pernet, Dr. J. M. H. MacLeod, Dr. Sequeira, and Dr. P. S. Abraham took part, various opinions being expressed as to the value and limitations of the procedure.

Dr. Little also brought forward a case of Folliculitis Decalvans of the Scalp of several years' duration in a lady aged 55, who also presented the condition of keratosis follicularis of about six months' duration in the axillæ, bends of the elbows, groins, and back; the latter lesions simulated those of Darier's disease, but the association with lesions of the scalp had not, as far as he knew, been reported.—The President, Sir M. Morris, Dr. Sequeira, and Dr. MacLeod, while agreeing with the diagnosis of folliculitis decalvans, were inclined to adopt the view that the lesions on the body were probably early Darier's disease, but Dr. Adamson expressed the opinion that the lesions of the latter disease were not essentially follicular.

Dr. Sequeira brought forward a patient suffering from Gummatous Syphilis and Diabetes Insipidus. He referred to several similar recorded cases as supporting the view that diabetes insipidus was commonly of syphilitic origin.—Mr. J. E. R. McDonagh pointed out that this correlation was more marked in congenital than acquired syphilis. He was inclined to attribute the condition to arterial disease.—Dr. Parkes Weber and Dr. Kinnier Wilson accentuated the relationship of diabetes insipidus to syphilis, the latter suggesting that the pathogenesis of the condition was a certain degree of basal meningitis with pressure in the floor of the third ventricle in the region of the pituitary body.

Dr. Wilson and Dr. Dore exhibited a case shown at a previous meeting of a man who had lived in the tropics and who had various patches of thermo-anæsthesia and other indications of a peripheral neuritis, as well as bullæ on the feet and thickening of the skin of the hands with nail changes. In their opinion the bulk of evidence favoured the diagnosis of leprosy.—Dr. Pernet accepted the suggestion of the exhibitors, but Dr. Abraham and Dr. MacLeod thought that further evidence ought to be adduced before accepting so grave a diagnosis.

Dr. Dore showed cultures from a case of Favus, which were discussed by Dr. MacLeod and Dr. R. A. Bolam.

Dr. Sibley demonstrated a typical case of Epidermolysis Bullosa or congenital tendency to the formation of bullæ from trivial injury in a woman aged 50. He referred to an apparently identical condition developing after traumatism during adult life.—The case exhibited was discussed by the President and Dr. Adamson, who had seen it on several occasions during the previous 17 years.

Dr. SEQUEIRA exhibited two Polish children with very extensive Favus of the scalp and trunk.

Dr. HALDIN DAVIS showed a girl with extensive Ulceration of the Face and Nose due to congenital syphilis, and asked for opinions as to the value of salvarsan and neo-salvarsan in such cases.—Dr. BOLAM, Dr. MACCORMAC, Dr. GRAY, and the PRESIDENT strongly advocated the use of salvarsan when the ulceration was active, but Dr. SEQUEIRA thought the administration of mercury by inunction and potassium iodide internally would be equally efficacious.

Dr. A. DOUGLAS HEATH presented a case of very unusual, extensive, deeply Pigmented and Atrophic Lichen Planus in a man, aged 56, which was said to have developed at the age of 3 months. On the hands the lesions were verrucose. Fresh lesions, which were constantly developing, were characteristic lichen planus papules, but there were no lesions of the mucous membranes.—Dr. Heath's views were generally accepted by the PRESIDENT, Dr. DORE, Dr. ADAMSON, and Dr. MACLEOD.

Dr. SEQUEIRA and Dr. JENKINS OLIVER showed cultures of Microsporon Ringworm from mother and child.

NORTH STAFFORDSHIRE MEDICAL SOCIETY.—A meeting of this society was held on April 15th at the North Staffordshire Infirmary, Dr. John Russell, the President, being in the chair.—Mr. A. W. Gill showed three cases of Congenital Heart Disease in children aged respectively 4, 8, and 9 years.—Mr. R. Alcock showed: (1) Sarcoma of Knee (pathological specimen); (2) Melon Seed Bodies from Compound Palmar Ganglion (pathological specimen); (3) patients undergoing treatment with Salvarsan; and (4) a case of Malignant Pustule.—Mr. S. McMurray showed cases of Congenital Nystagmus and Miner's Nystagmus.—Mr. W. Webster showed: 1. A woman exhibiting Sulph-hæmoglobinæmia or Enterogenous Cyanosis. 2. Two brothers with Myopathy of Pseudo-hypertrophic Type. 3. Large Tumour of Brain in Inferior Parietal Region, which gave rise to no localising symptoms. When the brain was removed post mortem a large gliosarcoma in the inferior parietal region was found. 4. A case of a young woman with Amyotrophic Lateral Sclerosis of Charcot. 5. Two Prostates removed by Freyer's method.—Dr. Harold Hartley exhibited patients suffering from (1) Secondary Cancer of Cervical Glands; (2) Lymphosarcoma of Neck; (3) a Myxoma of Bone (pathological specimen); and (4) a pathological specimen illustrating the complete operation for removal of a cancer of the breast.

LONDON DERMATOLOGICAL SOCIETY.—A meeting of this society was held at St. John's Hospital on April 20th, Dr. W. Knowsley Sibley being in the chair. At the clinical meeting which followed a series of cases were shown by Dr. Morgan Dockrell, Dr. J. L. Bunch, Dr. Sibley, Dr. Simonds Gooding, and Mr. C. H. Mills.—Mr. C. R. Kempster read a paper entitled "The Inhibitive Action of X Rays upon Malignant Growths," and showed a case of epithelioma affecting the tip of the nose which had been entirely cured by a few exposures to the X rays. He also exhibited photographs and microscopical specimens of a case of epithelioma of the leg which had also been cured by the X rays.—Dr. Dockrell, Dr. Sibley, and Dr. Gooding joined in the discussion.

ROSYTH AS A GARDEN CITY.—The construction of the Rosyth Naval Base had not proceeded far when the need for permanent dwellings in the vicinity of the works became apparent, and this need has grown more urgent as the scheme progresses towards completion. A desire was early shown to make Rosyth a community which should be free from the more sordid housing features that are found in most industrial centres, and negotiations to develop the area on garden city lines were carried on by local authorities, interested proprietors, and the Admiralty. A start is to be made in the near future by the Scottish National Housing Company, which is to build up 270 acres on lines approved by the Admiralty. As an initial step the company will put in hand 150 houses, to be rented at figures varying from £16 to £25, and architects have been asked to submit sketch plans for the scheme. The company's aim is to have the houses ready by October, and it is intended to erect about 3000 houses within the next five or six years.

Reviews and Notices of Books.

An Introduction to the Study of the Endocrine Glands and Internal Secretions.

By Sir EDWARD SCHÄFER, Regius Professor of Physiology, University of Edinburgh. Leland Stanford Junior University Publications. University Series. 1914. Pp. 94. Price 75 cents.

THIS monograph is published by Stanford University, California, and in it we have the Lane medical lectures delivered in 1913. Professor Schäfer is not, by the way, "Regius" professor, for the professor of physiology in the University of Edinburgh is appointed not by the Crown but by the curators of the University.

There is no one more competent to deal with endocrine glands than Professor Schäfer, who has contributed much to our knowledge of what was once a heterogeneous grouping of so-called ductless glands. The five lectures deal with (1) general considerations regarding internal secretions and the organs which furnish them; (2) the functions of the thyroid apparatus; (3) of the adrenal apparatus; (4) the pituitary body; and (5) the internal secretions of the pineal gland, of the alimentary mucous membrane, of the pancreas, and of the sexual glands.

The term "endocrine gland" is used by the author to indicate "an organ which is known to form some specific chemical substance within its cells and to pass this directly or indirectly into the blood stream." Instead of the term "internal secretion" the author uses the term "endocrine" to denote substances of a specific nature like the active chemical agents which are produced by the ductless glands. Specific active chemical agents are also passed into the blood by organs other than ductless glands—e.g., the pancreas. The author introduces certain new terms. As endocrine glands produce substances which cause depression or cessation of function as well as those that excite function—hormones—for the former the term chalone, from a Greek word "to make slack," is introduced. *Chalone* is "an endocrine product which inhibits or prevents the activity of an organ or tissue, as distinguished from a *hormone*, which excites the tissue to increased activity." The term hormone he employs in the sense in which it is used by its inventor. There is more nomenclature as represented by the general title "antacoid substances" or simply "antacoids." These are specific organic substances formed by the cells of one organ, which pass into the blood to produce effects upon other organs similar to those produced by drugs.

Descriptive details necessarily make up a large part of the text, but here and there the author offers much critical and suggestive comment. In Lecture II., which deals with the thyroid apparatus, we have additional new nomenclature. "The antacoid of the parathyroid ('parathyrine') is probably of chalonic, i.e., of inhibitory nature." The term "thyrine" is used to denote the active principle of the thyroid, "whether it is identical with, or contained in, the iodo-thyrin of Baumaunn or not." Another suggestion is made regarding the "chromaphil substance" of the medulla of the adrenals. As adrenalin "has a commercial attachment it is better to employ the neutral expression *adrenine* in place of it." The hypothetical antacoid supposed to be derived from the islands of Langerhans of the pancreas is called insuline.

The monograph gives an admirable, comprehensive, critical, and suggestive, yet not too diffuse account of the problems and practical importance of the now vast field associated with the terms ductless glands and internal secretions. There are no illustrations and but few references to the vast literature of the subject. There is neither preface nor index, but only the subject matter of the lectures themselves.

The Commoner Diseases, their Causes and Effects.

Translated from the German of Prof. Dr. L. JORES, of Marburg, by W. H. WOGLOM, M.D., Assistant Professor in Columbia University, N.Y. With 250 figures in the text. London and Philadelphia: J. B. Lippincott Company. 1915. Pp. xvi. + 424. Price 16*s*. net.

IN 1913 Professor Jores, at that time professor of pathological anatomy at Cologne, published an excellent volume containing 34 lectures on pathological anatomy, entitled "The Anatomical Bases of Important Diseases." This has been translated by Professor Woglom with considerable freedom, as his rendering of the German title *Anatomische Grundlagen wichtiger Krankheiten* may be taken to show, and with substantial success.

The lectures cover a great deal of ground, but are not unduly long or drawn-out. The first three deal with morbid conditions of the blood; then follow nine on vascular and cardiac disease, embolism, infarction, and bacterial infections of the blood. Various acute and chronic diseases of the lungs are next considered; tuberculosis of the lungs and other organs is described in four lectures. Without giving further details as to the contents of the book, one may say that it gives an accurate and well-proportioned view of both general and special pathological anatomy. It is designed for advanced rather than for early students of medicine, and is admirably calculated to supply the wants of medical practitioners who wish to bring up to date their knowledge of pathology. The illustrations are numerous, well chosen, and well reproduced; they are perhaps less sharply and brilliantly printed in the translation than in the original, because the paper used in the German edition is more white and glossy. The German original forms an admirable text-book for medical students who feel it necessary to learn to read German; its matter is sound, and its style is characteristic of the average German writer.

The translation by Professor Woglom is unusually happy; he has cut up and rearranged the often cumbrous and involved sentences of the German original with great skill, yet without the sacrifice of accuracy in the rendering. The price of the translation in England is the same as that of the original.

Investigation into Scrapie.

By J. P. M'GOWAN, M.A., M.D., B.Sc. Edin., M.R.C.P. Edin. With an appendix on a case of Johne's Disease in the Sheep. Edinburgh: William Blackwood and Sons. 1914. Pp. 116.

THIS book gives a history of the disease known as "scrapie" in sheep, and contains an account of Dr. M'Gowan's researches into the malady. The funds for the investigations were furnished by the Board of Agriculture for Scotland and were administered by a committee from the East of Scotland College of Agriculture and the Board.

In 12 chapters of 111 pages the author discusses the subject, describes his experiments, and advances his conclusions. The history of the malady in Britain, the disease as it is said to occur in other countries, and the symptoms and pathology of the complaint are given, and a case of the affection as seen in Germany has a chapter to itself. The remaining chapters discuss the different stages of sarcosporidiosis, which Dr. M'Gowan considers to be the cause of scrapie. He believes that two varieties of the disease exist, one marked chiefly by itchiness and the other by paralysis.

A period of about two years has been occupied in the investigation of the disease, and the researches have been exhaustive and thorough. The history of the research work, however, seems to be better and more exact than the history given of the disease. We are not convinced that louping ill is the same disease as the one known as scrapie. Louping ill has been the subject of a somewhat close investigation in previous years, notably in 1906, when the Board of Agriculture attributed it to a large, sporulating, rod-shaped bacillus. We also believe that the French *tremblante* and the German *Traberkrankheit* are identical with what has been hitherto known in this country as louping ill and not with scrapie.

The conclusions the author comes to with reference to scrapie are: 1. That the sarcocyst is always present in the skeletal muscles of scrapie sheep. 2. Pruritus, the chief symptom of scrapie, can be reproduced in rabbits by injection into them of sarcosporidial emulsions. 3. Clinical examination of typical cases makes it probable that the paretic symptoms are due to a primary muscle lesion. 4. The marked post-mortem condition of sarcosporidiosis can alone account for the phenomena of the disease. 5. No single view can explain so well the symptoms and general features of the disease as this. Two farms during the investigations furnished cases of Johne's disease in sheep with the usual naked-eye and microscopic appearances.

Dr. M'Gowan's research is very praiseworthy, and it may be gathered from his conclusions that medicinal therapy is useless in the disease. Regeneration of the flock and slaughter of affected animals early are the measures advocated. He considers that ewes can transmit congenital infection to the offspring and that the disease is not contagious. Some other authorities consider it markedly contagious. More research work is necessary in this disease, as indeed it is into other maladies of sheep, such as braxy and louping ill.

Local and Regional Anæsthesia.

With Chapters on Spinal, Epidural, Paravertebral, and Parasacral Analgesia, and on other Applications of Local and Regional Anæsthesia to the Surgery of the Eye, Ear, Nose and Throat, and in Dental Practice. By CARROLL W. ALLEN, M.D. With an introduction by RUDOLPH MATAS. Many illustrations. Philadelphia: W. B. Saunders Company. 1914. Pp. 625. Price 25*s*.

THE work that Professor Matas has done in connexion with local analgesia is so well known that a book such as this, which is practically an extensive exposition of his practice, is sure of a warm welcome from all those interested in the subject. Without any such preliminary call upon favour this book would still deserve a wide circle of readers amongst those who practise local methods of anæsthesia, for it is a comprehensive survey of the whole matter, which is well presented in the text and illustrated by many excellent diagrams and anatomical plates. Moreover, some of the side issues of anæsthesia are treated in a particularly full and interesting manner. There is, for instance, an excellent chapter on pain and a consideration of the various theories as to its intimate nature, whether it is to be considered as a separate sensation or as always an over-stimulation of ordinary senses. The author does not arrive at any definite conclusion on the point.

A chapter is devoted to anoci-association, and here we note that Dr. Allen does not favour quinine and urea chloride because it "produces massive fibrinous exudates in the infiltrated area with occasional tendency to suppuration." In some respects the book is almost too prodigal of detail, and we think that an unnecessary amount of space is taken up with the details of experimental work in connexion with arterial anæsthesia, a form of anæsthesia having no special claims, and one which, indeed, Dr. Allen does not himself recommend. The author is fond of the combination of alkaloids, generally morphia and scopolamine, both with local analgesias and with spinal analgesia. He gives an interesting account of the attempt to produce general anæsthesia through the intravenous use of local anæsthetics, and shows how enormous doses produce only imperfect analgesia, rendering the process impossible for human surgery.

There have been several large works published recently on local analgesia. Dr. Allen's is certainly not the least large of these, nor is it by any means the least useful. Though it would be all the better for pruning, it is a thoroughly valuable work.

LIBRARY TABLE.

The Way of the Red Cross. By E. CHARLES VIVIAN and J. E. HODDER WILLIAMS. With a preface by Queen ALEXANDRA. Published for the *Times* by Hodder and Stoughton, London, New York, and Toronto. 1915. Pp. 289. Price 2*s.* 6*d.* net.—Our country is fighting not alone for victory, or in defence of her plighted word, or to help to save Europe from the ideals of Bernhardi and from German "world-power," but also for her very existence; and it may be doubted if those who have to sit at home, whether from disabilities of age or other physical infirmities, or because they are needed in some form of work, do realise all that our brethren in arms, British, Belgian, French, Japanese, Russian, or Serbian, are undergoing. In the book now before us are a series of pictures drawn with a vivid and sympathetic pen of men and women, gentle and simple, military and civilian, all "doing their bit" earnestly and heroically because it is their duty so to do. Here we see the admirable organisation at work in the offices in Pall Mall, the doings in a base hospital in France, and can read talks with patients, nurses, and medical officers, which bring home to us the blessings conferred upon the victims of war by the Red Cross Society and the Order of St. John of Jerusalem. The tear and the smile are very near together in such chapters as "The Guardsman," "Soldats Belges," "Washing Up," and many another; but the note of the book is the unwearied patience of everyone concerned, whether in the fighting line, in the hospital, in the packing shed, or in the office. "In one day," said a clerk in the base hospital, "we had 2500 wounded in and sent 700 out to the hospital ship, and it's no use trying to explain the amount of clerical work that involves. But we had to get it done. And we did it." The Red Cross Society, which cheers the broken, helps the wounded and the sick, or, if that be not possible, smooths the way of those who are to die, cannot be carried on without material, however willing the personnel; and material means money. All the profits from the sale of the book are to go to the Red Cross Fund, but more is wanted now and much more will be wanted in the immediate future. If any reader can afford to send a contribution for the work it may be sent to the publishers, Messrs. Hodder and Stoughton, Warwick-square, London, E.C., marked "The Way of the Red Cross," and will be duly acknowledged in the *Times.*

Guida per il Medico in Guerra. By Dr. P. SISTO. Pp. 184. *Guida per il Chirurgo in Guerra.* By Dr. O. UFFREDUZZI. Pp. 197. Turin: Unione Tipografico-editrice. 1915. Price 2.50 lire each.—We are not inclined to think that army surgeons will derive a great amount of help from these little books, for the reason that anyone possessed of sufficient medical and surgical education to obtain commissions in the army will find them deficient in affording information as to the most recent improvements in the methods of dealing with injuries and diseases peculiar to warfare. Dr. Uffreduzzi gives some useful details with diagrams as to the arrangement with reference to the fighting line of field ambulances, and field and base hospitals. About three-fourths of the book deals with the treatment of wounds, both generally and in connexion with special parts of the body, and does not seem to recommend the use of antiseptics except to cleanse the skin around the wound. The following passage would probably not be endorsed by many military surgeons exactly as it stands: "Swabbing the wounds with tincture of iodine is useless and harmful, as is also the use of free ablution with sublimate and carbolic acid now universally abandoned." The author gives no rules as to the principles to be followed in accordance with varying conditions, but it must be allowed that those principles are only slowly evolving. He mentions the use of iodo-benzine to cleanse the skin, but does not allude to the practice of his compatriot, Dr. Guido Cremonese, of Rome, who recommends its free use in swabbing infected wounds. We welcome the advice to give prophylactic doses of antitetanic serum in lacerated wounds soiled with earth and horse excrement, as we believe that the occurrence of comparatively few cases of tetanus with the British army now in France is mainly to be attributed to this practice. A short résumé of the respective duties of the regimental surgeon, the ambulance officer, and the surgeon at the field hospital is, in our opinion, the best and most useful part of the book.

Dr. Sisto's book is a vade-mecum of the practice of military medicine compressed into a small and quite inadequate compass. Turning to a disease which has lately been attracting a great deal of attention among military surgeons, epidemic cerebro-spinal meningitis, we find no mention of retention of urine, which occurs frequently in cases where the cerebral symptoms are comparatively slight; neither under the heading of prophylaxis, which is dismissed in two lines, is there any reference to the supervision and isolation of carriers. We notice that most of the authors quoted for reference have names suggestive of Teutonic origin.

THE LANCET.

LONDON: SATURDAY, MAY 8, 1915.

The Medical Profession and the Needs of the Army.

THE cloud in which the various phases of the war are veiled combines with the far-reaching and complicated nature of the naval and military campaign to make the easy optimism of him who finds that all is always for the best nearly as hard to bear as the outbursts of our GUMMIDGES. Those, however, who resolutely take the broad view that against a powerful enemy there have been persistently opposed obstacles which, if they have as yet not been so obviously effective as had been hoped, have none the less produced in that enemy a dislocation of plan and a failure in great objectives, will know better than to impede the responsible leaders by criticism, made for the sake of criticism, or by useless regrets. But this does not mean that we must always applaud everything that is done, or must abstain from indicating where it appears that a thing might be better done. And we think that in regard to the help that remains to be rendered by the civilian medical profession to the army there is required from the War Office a frank explanation; for there is uncertainty at present. A feeling of doubt exists in the medical profession as to the further and urgent need of medical men with the army. There should be no two opinions in the case. Sir ALFRED KEOGH has most distinctly stated that he requires more men, and we know that the War Office is willing to do all that lies in its power to render any medical help that is offered available for the army, whether that help be general or special, whether it be proffered as whole-time or as part-time engagements. But there is not as yet a very definite plan for using the medical services of any save those who accept commissions unconditionally, and this has not been made obvious to medical men who desire, if possible, to help the military authorities and their country. They have never been told what is, as a matter of fact, the thing which they principally want to know—namely, that they will have to fit into the machine in the first instance, relying later upon showing by their work that the place where they find themselves could be exchanged with advantage to the general cause.

The call on the patriotism of the medical men who are now asked to join the army is indeed very great. The higher posts have been filled and a waiting list has been established behind their present occupants. What is required is medical men to join the army regardless of their civilian position and experience, in subordinate positions and, as a rule, with great sacrifice of income. The War Office cannot offer such men any commensurate return whatever; neither rank nor pay nor facilities for clinical research can often be based upon the special attainments or equipment of any medical man accepting a commission. We feel safe in saying that a man who possesses special qualifications in some direction will in the course of internal administration be, when practicable, placed where he seems to be exceptionally fitted. A skilled operator may be sure that as soon as opportunity serves he will be doing the operating surgery in his district, and a specialist will quickly find his particular services in demand. But at the beginning the War Office finds itself unable to go into individual claims. The principle of half-time employment is recognised, but only as secondary to whole-time service, and the call is really for compliance with the general pattern of medico-military duty. It is to the patriotism of the medical man that appeal is being made, and we are sure that the response will be forthcoming, but we feel that it would come more quickly if the reasons were officially stated why the offers of assistance must be practically unconditional. This war has been from a scientific point of view a triumph for medical men, and they may well feel that they deserve generous treatment. In our forces the freedom from disease has been wonderful, and the official manifestations of pleasure at the medical work done have been both ungrudging and thoroughly well deserved. But this must not blind us to the fact that while medical officers are an integral part of the army their work is dictated by military exigencies. One example which has recently been brought forward in our columns will exactly illustrate what is meant here. A scientific surgeon, on learning that he has to send back many of his patients to other hospitals before he has been able to judge the results of his treatment, and before, in his opinion, the patients are ready to travel, naturally experiences a sense of deep disappointment; but as an officer in the army he knows that the clearing of the beds has been made necessary because other casualties are expected to pour in; these must be received, and the beds are required in which to receive them. This is not a failure of scientific surgery; it is an adaptation of means to ends. The surgeon must not feel that he is being wasted: in certain cases he might do more good, but at the expense of wider profit to the Army. And the army as a whole must remain the chief thing. We doubt if it has been put sufficiently clearly to the doctors who have made applications to the War Office without success that they, urgently as their services are required, cannot be placed in the billets where they would be most useful individually, but may have to fill berths which they think unsuitable and where the duties may not appear nearly so important as the civilian ones, which, at heavy cost to themselves, they have resigned, so as to help in the general welfare of the army.

We have before us many letters from medical men very anxious to help in the national stress, who have been kept from volunteering because they have felt that their particular services were not in request. They do not seem ever to have been told that their particular services are not sought, but their general help. They have never been urged to join the army as a patriotic action. When a general practitioner of any standing unconditionally leaves his practice and accepts a lieutenant's commission he gives up so much that he has a right to expect that the measure of his sacrifice should be recognised by the country. The doctor who joins the army occupies a special position. He is a citizen whose actual professional civilian work is useful with the fighting forces; he is a layman whose equipment is necessary for military purposes. It is not a question of asking a doctor to give up being a doctor to become a soldier; during war, as a doctor he is a soldier. When the barrister or the stockbroker joins the army it must be very seldom that his experience in law court or counting house serves him as a fighting man. His action is as patriotic as that of the practitioner who joins the Royal Army Medical Corps, but the latter costs little or nothing to train, and this should be recognised. There is no doubt that more doctors are and will be wanted for the army—signs of local plethora mean nothing. And we believe that the army will obtain the number of medical men needed, however great that number may be, and however dangerously depleted the ranks of civilian medicine may thus become. But we would urge upon the authorities that the case of many of those who will be taking commissions calls for generous appreciation of their self-sacrifice and a clear explanation of the demands made upon them.

◆

The Registrar-General's Report for 1913.

THE seventy-sixth annual report of the Registrar-General has recently been presented to Parliament. The document relates to the births, deaths, and marriages in England and Wales during 1913, and as it has only been available to the public within the last few days our readers will not unreasonably look for some explanation of its late appearance. In a prefatory note Mr. BERNARD MALLET expresses his regret that this report, relating as it does to 1913, should not appear until the spring of 1915, as he fully recognises the importance of prompt publication of the data in question, considered as a permanent record of vital statistics. Having regard to the delay in the issue of the two preceding reports—caused partly by the requirements of the Census and partly by the extensive changes of form and matter inaugurated in the report for 1911 — the Registrar-General hoped until recently that, the disappearance of these two causes of delay having been achieved, a much earlier publication of the present report would have been secured—not later than 12 months after the completion of the year to which it refers. The realisation of this hope has, however, been prevented by the war, which has had the combined effect of reducing the expert staff of workers in the department, and of imposing new duties on the remainder. We are assured, however, that unless the interference due to war is further increased a definite improvement may be expected in the date at which the report for 1914 will be available to the public.

In view of the special circumstances of the time the advisability of curtailing the present report was considered; but this course was, as we think wisely, rejected, because of the consideration that the value of a series of annual tables would be seriously impaired by any interruption of its continuity. Consequently, all the important tables in the last two reports have been repeated in the present. The Registrar-General expresses the opinion that while tables of primary importance ought to appear annually, and in as constant a form as circumstances permit, it will be advantageous to vary from time to time both the subject matter and the manner of treatment of other portions of the report. Whilst, therefore, matters of prime importance will henceforth be given every year, the records of other matters of less, though still considerable interest will be published for "sample years" at intervals, the subjects so dealt with being varied from year to year in order to increase their number. This is a departure which will much enhance the value of these reports. Speaking generally, the vital statistics of the year 1913 are distinctly favourable. It is satisfactory to note that both in 1912 and in 1913 the marriage-rate showed a further increase on the rate in the preceding four years, the provisional figures for 1914 indicating a still further rise. The birth-rate, however, failed to show any recovery. The death-rate in 1913, although somewhat higher than in 1910 and 1912, was otherwise the lowest on record. Apart from the effects of the warmer summer, the reduction of mortality below all previous records which characterised 1912 was maintained throughout the year now under review.

As 1913 was the last complete year preceding the outbreak of hostilities, the statistics in this report concerning the British army and navy will be studied with interest, if only as affording a basis of comparison with the less favourable figures which must be looked for in subsequent reports giving the results of the existing European War. Highly significant in this connexion is the fact that the average regimental strength of the British army was actually lower in the year under notice than it had been at any time since 1899. The health of the army, both in the United Kingdom and abroad, appears to have been maintained at a high standard. Particulars concerning the Royal Navy do not readily admit of comparison with those of the sister service. Nevertheless, the health of the service afloat is shown to have been satisfactory for several years past. Equally interesting for purposes of future comparison are the details of casualties in the British merchant service, especially those resulting from the destruction of vessels which may be expected to recur in the event of the continuance of the present conflict. From particulars furnished by the Marine Department of the Board of Trade it appears that in the year 1913 masters and seamen employed in the merchant service were more numerous than at any previously recorded period, whilst the mortality from disease, wreckage, and other casualties compares favourably with that of previous years. In this case especially the records of future years will enable some measure to be derived of the serious loss of life now being wantonly inflicted on our non-combatant sailors by the piratical conduct of the enemy.

Annotations.

"Ne quid nimis."

EFFECT OF THE SPIRIT TAX ON THE COST OF MEDICINAL COMPOUNDS.

ONE of the unintended consequences of the spirit duty has always been to impose a heavy burden of taxation on a large and important class of medicinal compounds, for alcohol is more extensively employed in the manufacture of galenical preparations than any other substance. A very high proportion of a hospital drug bill is in respect of the duty on spirit, and the same, of course, applies to a pharmacist's account with his wholesale house. This was the case under the rate of duty in force before the increased duties were proposed on spirit last week, and it is therefore obvious that the tax on spirituous medicines will be double the previous tax unless some concession is made in the case of medicinal spirits. Under the old duty a hospital using a hundred gallons of rectified spirit a year paid something like £115 in respect of the duty on alcohol, while at the new rate the duty would, of course, be £230. Some of the large London hospitals use 200 gallons of rectified spirit a year, and in exceptional cases more than this amount, so that the tax is a very serious matter indeed. In introducing his proposals in the House of Commons on April 29th the Chancellor of the Exchequer intimated that he was anxious to exempt medicinal spirits from the increased tax, and that he was endeavouring to devise a means of making an exception in the case of such spirits. In the past Mr. Lloyd George, as well as his predecessors, when urged to differentiate between potable spirits and alcohol used in the manufacture of tinctures and like preparations, has refused to do so on the ground that it has been impossible to formulate a practicable scheme to prevent fraud; but with a tax of 29*s.* 6*d.* a gallon on proof spirit and 46*s.* a gallon on rectified spirit it is urgently desirable that the Excise authorities should exercise all their ingenuity in devising a plan by the operation of which medicinal spirit may be freed from the extraordinarily heavy burden of taxation without loss of revenue by the fraudulent use of spirit. The case for a rebate of the duty on medicinal alcohol is equally strong from the point of view of the Insurance Act Drug Fund as from that of the hospitals. The problem is admittedly a very difficult one, but there is some hope that a satisfactory solution will be found.

TREATMENT OF TUBERCULOSIS.

THE Local Government Board have issued two circulars in reference to the arrangements to be made for the treatment of tuberculosis. One is addressed to the metropolitan borough councils and the other to the councils of counties and county boroughs (England). Their contents are similar. In reference to tuberculosis officers, the Board refer to the fact that some tuberculosis officers are absent on naval or military duty, and that their absence should be duly reported. Further, the councils are reminded that at the present moment it may be difficult in all cases to secure that tuberculosis officers should have the additional qualifications which were recommended. It is only right that relaxation of certain rules should be permitted at the present time, when the needs of the nation call for all medical men that can be spared; indeed, it might well be upheld that the younger officers should be encouraged to obtain temporary commissions in the Royal Army Medical Corps, their appointments being held open for them and their duties in the meantime being carried out by older practitioners. The Board also point out that they have had under consideration the question of the provision by local authorities of nursing for persons suffering from tuberculosis who are being treated in their own homes. The Board rightly recognise that the provision of skilled nursing for some of these cases forms an essential part of the treatment, and we trust that in the future suitable arrangements will be made; but it is pointed out that the need of nurses for military purposes will for the time being preclude any extension of the nursing service in this direction. Another important matter referred to is the organisation of voluntary committees for the care of patients suffering from tuberculosis. The Departmental Committee on Tuberculosis expressed the opinion that the effectiveness of the dispensary could be greatly increased by the formation of such committees consisting of representatives from the local authorities, boards of guardians, Insurance Committees, and from all charitable and social work organisations in the district. The assistance such committees could give would be great, such as the provision of additional food, change of air, clothing, suitable occupation, and so on. The circular points out that much of the work to be so undertaken would be outside the powers of local authorities, and the committees would have to rely largely on voluntary contributions. But with careful organisation the help thus afforded would be great. The experience of sanatorium officials goes to show that the ultimate result of the treatment at such institutions largely depends upon whether the patients can be placed in healthy environment and find suitable occupation after their discharge. In a large number of cases this is most difficult of accomplishment, and consequently many relapses occur. We cordially support the recommendation of the Board that such committees should be formed with as much support as possible from the borough and county councils.

FROM GERMAN MEDICAL JOURNALS.

RECENT numbers of the *Presse Médicale* have contained interesting excerpts from current German medical journals which deserve to be brought to the notice of the medical profession in England. In one of the January numbers of the *Deutsche Medizinische Wochenschrift* Dr. Loewenfeld, of Munich, a neurologist, published an article on the national character of the French and on its psychopathic traits as evidenced in the present war. He declares that the specific psychological characteristics of the French are vanity, ostentation, carelessness for truth, exaggerated emotivity, and an innate tendency to cruelty, as seen, for instance, at the time of the Terror and the Commune, and as exemplified by "the brutalities of which the Germans and Austrians have been the victims since the present war began." The delicate comments of the French editor on this profound analysis of the racial character of his people can be imagined. It is not necessary, unfortunately, to go back to the days of Tilly or Wallenstein to find proofs of German cruelty; the hecatombs of Belgium do not date back to the Terror, or even to the Commune. Yet to read the puerile communication of the German neurologist one might suppose that the deliberate and methodical application of a system of terrorisation, on a colossal scale, as an integral part of the German conception of war, advocated in all frankness by its exponents, had never even been devised, still less carried into effect. In a February number of the same journal Dr. Erich Hesse, attached as "Hygieniker" to the 19th Army Corps, explains the excellent general condition of the troops under his own more immediate observation as due in great part to their supplies of French red wine. A solemn explanation of how these immense stores came into their hands—"the inhabitants had fled owing to fear of well-merited punishment"—is followed by an equally serious appreciation of the great self-restraint of his soldiers in so rarely "exceeding the bounds of decency." Their good health, their resistance to the petty hygienic troubles of the trenches, the favourable evolution of intestinal catarrhs, &c., are all attributed to the same cause. "Ah! le bon vin rouge de France!" says the French editor by way of comment. There have been many articles dealing with venereal disease in the German medical journals. In the *Deutsche Medizinische Wochenschrift* of Jan. 14th Professor Neisser, of Breslau, says that the figures of 70·6 per 1000 cases treated in hospitals during the Franco-German war of 1870, as representing the proportion of venereal cases, have already been largely exceeded in the present war. After remarking that an appeal to the honour of the heroes of Louvain and Flanders would be sure to have a deterrent effect (Man könnte aber gewiss mit Grösserem Erfolg an das Ehrgefühl unserer Truppen appellieren), he nevertheless makes the following proposals to deal with the situation: (1) imprisonment of all prostitutes that can be discovered; (2) energetic prophylactic treatment with salvarsan and mercury of all women "suspected" (*sic*) of prostitution; (3) the distribution of suitable protective appliances to the armies of occupation. Anyone conversant with French journalistic levities can imagine for himself the chance thus afforded for an expression of caustic humour. Neisser's proposals have been followed by numerous criticisms and counter-suggestions in the columns of the same journal. Dr. Kurt Mendel (of the *Neurologisches Centralblatt*) can find no remedy for the extremely widespread infection but absolute continence. Others make proposals for the regulation of this traffic which are on a par with their methodical and well-organised arrangements for the distribution of bread tickets. At a "Kriegsärztlicher Abend" held at Lille on Jan. 20th (*Münchener Medizinische Wochenschrift*, Feb. 9th), and attended by some 200 military medical men, it was proposed to distribute appliances to the troops by means of automatic machines. Complaints were also made of the behaviour of the women in the Germans' hands; and here a passage, in its nauseating frankness, may be given in the original: "Selbst die bessere französische Prostituierte halt sich den Deutschen fern: es kommen fast nur die niedersten und schmutzigsten Prostituierten in Betracht, die man sich denken kann. Sie sind eine gefährliche Infectionsquelle, weil sie alle Reinlichkeitmassnahmen, die die bessere Prostituierte durchfürt, missachten. *Daneben gibt es Frauen, selbst mit 4 und 5 Kindern und Mädchen, die sich aus reiner Not, um ein halbes Stück Brot den Soldaten anbieten.* Diese Neulinge der Prostitution sind besonders gefährlich, weil sie die Hauptträger der Infectionsquelle werden." As the French editor truly says, what human being can read without horror and disgust the unconscious revelation of a world of infamy contained in these lines?

THE ETIOLOGY OF RICKETS.

IT is somewhat remarkable that in a disease so widely spread and so common as rickets there should still remain so much that is enigmatic, or, at any rate, controversial in its etiology, in spite of careful clinical and experimental research in this and other countries. The whole subject of the etiology of this condition is reviewed in an interesting and critical manner in a paper by Dr. Leonard Findlay, which we publish in this week's issue of THE LANCET. He points out that in this country and in America, following the interesting observations of Sir John Bland-Sutton at the Zoological Society's Gardens some years ago, the dietetic factor in the etiology has received a great deal of attention. It is natural, since this disease can apparently be induced in some animals under experimental conditions, that considerable importance should attach to such observations; but Dr. Findlay rightly points out that it is essential that the truly rachitic character of the lesions induced in animals should be established by microscopical examination. Moreover, he points out further that there is a metabolic disturbance in rickets in the human subject, notably in regard to calcium salts, an important fact which is often lost sight of. It would appear that there is an inability on the part of the body to use this substance, even though present in the diet in sufficient amounts. The theory that this depends upon some hormonic defect is a tempting one, but is not at present definitely established. It has long been recognised that there is probably a hygienic factor in the causation of rickets, since the disease is so much more common in towns and in the older countries than in the country and in newer settlements. Dr. Findlay, on the basis of some experimental observations previously published, arrived at the startling and heterodox conclusion that there was no evidence that deficiency of fat, or, indeed, any error of diet, was a factor in the etiology of rickets. He found that the important factor in animals was the deprivation of exercise. He now supplements his observations in this respect by an interesting examination of the dietetic and hygienic conditions of between 400 and 500 rachitic children. He shows charts demonstrating that neither the want of breast-milk nor prolonged suckling exerts any definite influence on the incidence of rickets among the cases examined—an interesting refutation of the suggestion that dietetic factors are of paramount importance or that artificial or patent foods are causal agents. Some observations upon the occurrence of intestinal disturbances prior to the onset of the disease do not appear to lend support to Marfan's view that an intestinal auto-intoxication is the cause of the condition. An analysis of the cases according to the level of their homes above the ground revealed no important fact. A study of the amount of air-space allowed in the home to each child demonstrates that the less air-space the greater the incidence of the disease. Lastly, the amount of time spent in the open air is studied in regard to these children and reveals the interesting fact that a considerable proportion of these children are not taken out at all. Dr. Findlay believes that the two factors, confinement and deficient fresh air, render the child lethargic and diminish the amount of muscular exercise obtained, and further suggests that deficient exercise affects the metabolism of calcium, a thesis for which there is some experimental support. On the basis of his observations he advises massage, passive movement, and electricity in the treatment of the disease. We commend his paper to our readers as a thoughtful and suggestive piece of work.

THE PATHOLOGY OF LEPROSY.

THOUGH many points in the pathology of leprosy remain unsolved, it cannot be denied that the experimental investigations carried out during the last few years have thrown considerable light upon this difficult subject. In the current number of the *Annals of Tropical Medicine and Parasitology*, Vol. IX., No. 1, a very interesting and timely summary of the present state of our knowledge of leprosy, and the results obtained concerning it by experimental studies, has been contributed by Dr. H. Bayon, research bacteriologist to the Government of the Union of South Africa. The author has discussed the whole question of the clinical and pathological features of the disease, its specific organism, the experimental transmission of the infection to animals, and the relation of spontaneous rat-leprosy to the human disease. He has also dealt with serological tests and reactions in leprosy, and the degree of communicability of the infection. He has something also to say concerning the treatment and prophylaxis of the malady. It is gratifying to find that Dr. Bayon views hopefully the prospect of the ultimate extinction in time of this terrible disease. As regards its communicability, he believes that the evidence which has been accumulated justifies the conclusion that the usual mode of infection is by direct or indirect contact, especially under unfavourable hygienic circumstances, including overcrowding and lack of personal and domestic cleanliness. Intimate contact, such as that between mother and child, or sleeping in the same bed with a leprous person, supplies the requisite conditions for the transference of the disease. In countries like South Africa, where leprosy is not uncommon and where native servants or nurses are employed to wait upon white children, the danger is greater than some authorities have been inclined to admit. It is pointed out that the disease may exist in a native servant for a long time before its presence is recognised by the employer. Instances are mentioned where infection is believed to have followed upon the common use of drinking-cups or other vessels. Although Dr. Bayon regards as "far-fetched" the suggestion that a biting insect may act as the intermediary in the transmission of leprosy, he nevertheless admits the possibility that the common house-fly may suck up germs of the disease from leprous sores and transfer them mechanically to a healthy human subject. In this connexion those who have travelled in the East cannot fail to have been struck with the frequency with which flies swarm upon the open sores and round the nostrils of leprous beggars. With respect to spontaneous rat-leprosy, it presents numerous points of resemblance to the human malady, and the experiments which have already been made suggest that it may be etiologically related to that form of the disease from which man suffers, the relationship being possibly of a similar kind to that which exists between bovine and human tuberculosis. As regards treatment, Dr. Bayon reminds his readers that the macular variety of leprosy is subject to spontaneous remissions and apparent cures without the aid of any remedies. Chaulmoogra oil seems to be indicated for the nodular form of the disease, and as far as present experience goes, cultural extract may be usefully employed for the macular cases. With respect to prophylaxis, the measures recommended include registration and sanitary inspection of the homes of lepers, but segregation of the sufferers in asylums, settlements, or colonies is strongly urged; early separation of children from their leprous parents is necessary, and the strict enforcement of personal and domestic cleanliness, along with the abolition of overcrowding, must be carried out in localities where leprosy is known to be endemic.

INVALID CHILDREN'S AID ASSOCIATION.

THE Invalid Children's Aid Association held its twenty-seventh annual meeting on April 28th, Field-Marshal Lord Grenfell presiding. Three resolutions were submitted to the audience. The first, proposed by the chairman, was in favour of the approval and adoption of the annual report, and as Lord Grenfell pointed out, this report showed the excellence of the work done by the association, and the steady spread of its activity. The association now has 20 branches at work in London, and nearly 40 more provincial branches, most of them federated to the London Association. As evidence of the activity of the London branches, Lord Grenfell quoted the fact that in 1914 over 8000 invalid children were assisted by convalescence, surgical instruments, or whatever particular form of medical or surgical aid their medical attendants had ordered; while the sum of over £15,500 was expended in giving this aid. A second resolution, pledging financial support to the association, was proposed by Countess Ferrers, who spoke eloquently of the assistance so freely given by the association. A third resolution recommending the re-election of the association's council and executive committee was proposed by Lady Jellicoe, who instanced the number of former Invalid Children's Aid Association "cases" now serving their country at the front or on the waves as conclusive evidence of the excellent work it does. It had been hoped that Captain Francis Grenfell, V.C., would have been able to be present at the meeting and to speak. This was impossible, as he was actually serving at the front; but his letter expressing his regret at being unable to be present, written from the trenches near Ypres, was read out, and made a most moving appeal to its hearers. Year by year the work of the association increases, and year by year the difficulty of collecting the funds grows; but the association is favourably known to so many medical men that the public ought to feel sure that the money given does good medical service.

ASPERGILLOSIS OF THE NASAL ACCESSORY SINUSES.

Mr. Herbert Tilley has published in the *Journal of Laryngology, Rhinology, and Otology* for April five cases of aspergillosis of the maxillary antrum. The rarity of the condition is intimated from the fact that there can be found no mention of it in the literature of rhinology; it is suggested, however, that this condition may have been overlooked. Myxomatous disease is most likely to be confused with it. The mode of infection with the aspergillus mycelium is not known; it may be grafted upon a chronic inflammatory infection of the antral mucous membrane. Marked nasal obstruction is a prominent feature, and this is associated with sneezing and the discharge of a mucoid or slightly muco-purulent fluid. There may be neuralgic pains in the cheek and face. Especially important for diagnostic purposes is the occasional expulsion of small masses of a whitish-grey, semi-translucent, viscous material. In no instance is the discharge so free as to suggest an ordinary, chronic empyema. On examination the most striking feature in the cases seen was the pale, swollen, and œdematous condition of the nasal mucous membrane; and, further, this was not overcome by the application of 20 per cent. solution of cocaine. In no other disease, says the writer, is the lack of response to cocaine so marked. Transillumination revealed opacity in both infra-orbital regions. It was impossible, also, to get any return of fluid on irrigation. These points are all suggestive of this condition and diagnosis is assured, of course, with the discovery of the mycelium. This, however, is often a matter of some difficulty. In the instances here recorded Professor S. G. Shattock had undertaken the examination. In the mucin examined there pervades a well-developed mycelium, the coarseness of whose filaments at once excludes actinomycosis. There are, of course, also collections of bacteria which are, however, much less widely distributed than would be expected. The mucin is probably secreted under irritation and is subsequently inspissated and the contained cells are polymorphonuclear leucocytes. It is curious to note, finally, the presence of crystals resembling the Charcot-Leyden crystals found in asthmatic sputum.

WE regret to announce the death of Sir William Richard Gowers, M.D. Lond., F.R.C.P. Lond., LL.D., F.R.S., which took place on May 4th at his residence, 34, Ladbroke-square, W.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

ANNUAL CONGRESS.

(*Concluded from p. 930.*)

AT the annual congress of the Ophthalmological Society of the United Kingdom two set discussions were arranged. The first, upon Ophthalmic Injuries in Warfare, introduced by Mr. W. H. H. Jessop, was reported last week. The second, on Detachment of the Retina, was introduced by Mr. M. S. Mayou.

Detachment of the Retina.

Mr. MAYOU, in introducing the set discussion on this subject, said that detachment of the retina was only a sequel to other intraocular diseases. He dealt in the first place with its associated physical phenomena, and secondly with congenital detachment especially. The condition was really one of separation of the retina between the pigment-cell layer and the rods and cones—i.e., where the two layers of the optic cup come together during fœtal life, and which was subsequently represented as a lymph space. Detachment of retina was essentially a cystic condition. He was strongly in agreement with von Graefe's view that it was exudative in origin, and that detachment could not occur without fluid being effused from the choroidal vessels, the fluid having a higher specific gravity than that in the vitreous chamber. It was probable that there was no true tissue adhesion between the rods and cones and pigment-cell layer, or at least so slight that it was not a factor in keeping the retina in its place. This potential space was filled with lymph, permitting the rapid tissue change associated with the bleaching and regeneration of the visual purple. In the normal eye distension of the vitreous in its hyaloid was by fluid derived from the ciliary process; the vitreous exerted a pressure by having a higher density than the lymph in the inter-retinal space. In many diseases the vitreous became more fluid than normal, or the framework of the vitreous shrank with the hyaloid, and there was free fluid in the space between hyaloid and retina. With degeneration of the vitreous the densities of the fluids on the two sides of the membrane closely approximated, and a slightly increased density of that in the inter-retinal space would produce detachment. For the investigation of such cases it was necessary to use a fixing agent which coagulated but did not destroy albumin, and boiling was the best. It was very difficult to ascertain the underlying cause of shrinkage of vitreous. Detachment of retina occurred when a larger pressure was exerted outside than inside the membrane. Detachment could occur with a normal vitreous, as when the choroid was the seat of a growth. Owing to the effusion of albuminous fluid the retina was pushed inwards, and some of the fluid was squeezed out of the connective tissue meshes, passing forward into the anterior chamber. Glaucoma might supervene before the complete shrinkage of the vitreous. Detached retina associated with growth in the choroid was exudative in character, though it might cause secondary changes in the vitreous. He detailed some cases in children who had come under his care. In myopia a fluid exuded into the inter-retinal space of low density would cause detachment, possibly associated with venous obstruction. Inflammatory exudation from the choroid might cause detachment if of serous rather than plastic nature. Injuries might cause detachment, either with or without perforation of the globe. Fibrous bands in the vitreous, he thought, rarely caused detachment by contraction, though they might predispose to it by causing shrinkage and fluidity of vitreous. Cysts in the retina in its normal position might be of considerable size and, by bulging, cause detachment on either side. Some of the cures of detachment, he thought, were probably due to evacuation of the fluid contents of these cysts. Congenital detachment was not usually recognised, as it occurred in microphthalmic eyes, and was not then seen clinically. Summarised, his contention was that the essential feature in congenital separation between the layers of the retina was distension of the primary optic vesicle with fluid, and that the fibrosis of the vitreous was of secondary development, not the cause of failure of union between the inner and outer layer.

Mr. Leslie Paton pointed out that so long as the pathology of any disease was obscure its treatment must be empirical and frequently ineffectual. This was the present-day attitude in regard to detachment of retina, which was really a terminal effect. In cases of tumour of choroid detachment was caused by accumulation of œdematous fluid behind the retina, this fluid being an irritative product. In some cases the cause was a perforating wound of the sclera, a case of which he quoted. Sometimes the detachment was due to a rapid exudation of lymph and serum into the sub-retinal space in severe choroiditis or general uveitis; or it might be caused by subretinal hæmorrhage. He believed that detachment might occur from cicatricial contraction of the retina itself. From an examination of different types he thought it safe to conclude that symptomatic detachment might arise from either a push from behind, a pull from inside, contraction of the retina, or a combination of any of these factors. He reminded the meeting of the main contentions of Raehlmann and Leber, and said that most cases of simple detachment occurred in myopes; he had found it to occur in all degrees of myopia, in which condition there was an increased cubical capacity of the scleral cavity. Vail, of Cincinnati, had shown that in myopes the circular ciliary muscle was usually atrophied from non-use, and that authority considered it part of a generalised atrophy of the ciliary body, with diminution of aqueous secretion and lowering of ocular tension. Mr. Paton then proceeded to discuss the question of sympathetic detachment, stating that he considered it a moot point as to whether it was really sympathetic, or whether the action was a setting up of a chronic cyclitis or uveitis in the sympathising eye. He had had some cases of cure—i.e., restoration of function; and he realised that spontaneous cure sometimes eventuated, though similar cases left alone had not got well, as had the cases in point after his treatment. In every case he thought all the facts should be placed before the patient, so that he could decide on whether he would have anything done or not, especially as knowledge on the subject was not yet complete enough to enable a safe prognostication to be made in any particular instance.

Dr. A. Maitland Ramsay, reviewed the literary landmarks. He agreed with Mr. Paton that no theory of causation of detachment sufficed to account for all the cases; the underlying cause in all was disease of the uveal tract and of the pigment epithelium, though this might be nothing more than senile degeneration. The presence of a collection of fluid between the choroid and retina led to many forms of evacuation, which were briefly indicated—38 in number. The most important factor in the treatment he considered to be absolute rest in bed; patients often volunteered the statement that they could see best in the morning after a good night's rest, but that sight failed as the day advanced. The rest period should not be less than four to six weeks. Relapses occurred most frequently in those who had rested but a short time. Every effort should also be made to improve the patient's well-being, particular attention being bestowed on procuring regular action of the bowels, kidneys, and skin. Next the pressure bandage was important; both eyes should be covered and the pressure must be quite appreciable, though stopping short of pain. But where the bandage caused pain, and on its removal the eye was red and irritable, it should be discontinued, owing to the possibility of irido-cyclitis supervening. Cases which did not bear the pressure bandage he regarded as of unfavourable prognosis. The third important factor of treatment was subconjunctival injections after 48 hours of bandaging, but only if the electric ophthalmoscope showed that the site and character of the detachment appeared favourable. The pain following the injections (which he detailed) was mitigated greatly by using chemically pure chloride of sodium. Diaphoresis he did not employ until a fortnight's trial by his other methods showed little or no improvement. In some cases diaphoresis started an improvement which became slowly progressive. He used pilocarpine for this. There should be a period of leisurely recuperation afterwards; resumption of businesss immediately after cure seemed to invite relapse, and this was also helped by constipation. Failure was almost certain when the choroid was extensively diseased, when the pupils were sluggish in responding to mydriatics, and when intraocular tension was greatly reduced.

The debate was continued by Sir Anderson Critchett, Mr. E. Treacher Collins, Mr. R. R. Cruise, Mr. J. B. Lawford, Mr. Sydney Stephenson, Mr. D. Leighton Davies, Mr. P. W. Maxwell, Mr. J. B. Story (Dublin), Mr. C. Higgens, Mr. G. Mackay (Edinburgh), and the President and the authors replied.

Mr. Cyril Walker read a communication on

Angiosarcoma of Retina.

The patient, aged 4 years, was seen on Nov. 11th, 1914. Eight months before there was said to have been a film over the right eye; no pain or redness. It disappeared in about six weeks. In June and September there was some pain in the eye, but the boy had regularly attended school to the end of October. The right eye was seen to be the seat of a brownish-yellow hypopyon. There was no ophthalmoscopic reflex; the tension was normal, and the pupil dilated well with atropine. There was doubtful perception of light. The left eye was normal, and the patient's general condition good. Ten days later the eye became red and tender and there was some continuous pain; the tension was *plus* 1. The contents of the anterior chamber were evacuated, and Professor Walker Hall reported that the material was probably sarcomatous. The eye was accordingly excised and submitted to the same authority. Early in December some three-quarter inch of the stump of the optic nerve was removed, with a mass of tissues surrounding it. Pathological examination showed that recurrence had commenced in the stump of the nerve and the surrounding tissues, but there was a small margin of healthy tissue. Mr. A. Osborne, of Ilfracombe, reported that recurrence took place within a fortnight of the second operation, and that the mass had attained the size of a cocoanut. The boy's mental condition was not affected, and there had been no metastasis. The specimen showed that the ciliary region was not invaded.

Clinical Meeting.

At the clinical meeting at the Royal London Ophthalmic Hospital the following cases were shown:—

Mr. J. Gray Clegg (Manchester): Case of Bullous Keratitis, whose sister was similarly affected.

Mr. Sydney Stephenson: (1) A case and drawing to illustrate Coarse Striate Clearing of a Corneal Cicatrix; and (2) a case of Blue Sclerotics.

Mr. C. Wray: (1) Cases operated on for Conical Cornea; (2) drawings of Cured Conus; and (3) Exostosis of the Orbit (two cases).

Mr. E. Treacher Collins: (1) Case of Congenital Ectropion of both Lower Lids; (2) Double Facial Paralysis; (3) Detached Retina cured by rest in bed and scleral puncture; and (4) Aphakia with apparent accommodation.

Mr. Leslie Paton: Cases of Healed Detachment of Retina.

Mr. W. T. Holmes Spicer: Congenital Cataract and Spontaneous Dislocation of Lens in three members of the same family.

Mr. J. Attlee: Peripapular Ectasia.

Mr. Rayner Batten: Collapsible Periscope.

Mr. W. H. H. Jessop: Acute Central Retinitis.

Mr. G. H. Pooley (Sheffield): Extensive Pigmented Moles of Face, Eyelids, and Conjunctiva.

Mr. R. Foster Moore: (1) Two instances of Disappearance of a Detachment of the Retina in Patients with Albuminuria; and (2) Pigmented Mole of rapid growth.

Mr. Cyril H. Walker (Bristol): Hyaline Bodies at the Optic Disc.

Mr. A. C. Hudson: Iridescent Corneal Scar.

The President (Mr. F. Richardson Cross) read a paper on

Eye Symptoms in Kaposi's Disease (Xeroderma Pigmentosum).

In a general review of the disease he stated that spots like freckles appeared in the first year or two of life, and were often precursors of the grave skin disease described by Kaposi in 1870, accompanied by dryness and atrophy of the skin, and other serious changes. Frequently more than one member of a family were affected. The prognosis was very gloomy; early death might occur from deep ulceration towards the brain or other vital parts; or from exhaustion or hæmorrhage. The muco-cutaneous surfaces, such as the eyelids, became thinned, shrunken, and fissured with superficial ulcers ; and the eyeball might participate in any phase of the disease, and warts might occur on the lid edges. The ocular conjunctiva was usually hyperæmic. Some cases showed pterygium, and the cornea became hazy from infiltration of its substance or from swelling of the epithelium. Ectropion was frequently present, leading to opacity or ulcer of cornea. But in many cases the eyes were open and light was well tolerated. The optic nerve and intraocular structures were affected only late, if at all. Massage of the eyeball, especially by the use of calomel ointment, served to empty the superficial blood-vessels. Dr. A. Whitfield had much improved one such case by applying X rays. During the past year Mr. Cross had had under observation two cases of Kaposi's disease, brother and sister, aged 11 and 9½ years. The parents (cousins) were healthy. The boy was born in Ceylon, and when coming to England at nine months old he became very sunburnt in the Red Sea, his skin becoming scarlet. Later the face, neck, and shoulders were dotted with yellowish-brown pigment spots, and the skin became thin and shrunken. The girl was born in England and arrived at Ceylon when a few months old ; in her voyage she did not encounter excessive sun-glare. At nine months of age her skin also became bad, and a little later a small nodule appeared on the cheek but fell off, leaving no scar. She had implication of the eyelids, causing eversion. When four years old the boy had a troublesome papule on the eye, for which he was treated by Sir John Tweedy, who reported that he first saw the patient in April, 1907, when he was under the care of the late Dr. Radcliffe Crocker for the skin condition. At that date there was subconjunctival ecchymosis at the outer side, and at the inner side of the globe, between the cornea and the caruncle, a truncated conical swelling with some ecchymosis and conjunctivitis. There was so much photophobia that a satisfactory view could not be obtained. On the following day, under a general anæsthetic, he examined the eye and found an indolent swelling in the conjunctiva and episclera at the inner side of the globe. He scraped it with a sharp spoon and applied powdered salicylic acid, and ordered the eye to be washed two or three times a day with a solution of salicylate of soda. The eye gradually improved until the seat of the swelling presented the appearance of a small phlycten. Eighteen months later, when Sir John Tweedy next saw the case, the eyes were much stronger and were rarely inflamed. Two and a quarter years later the patient saw J. 2 with correcting glasses. When Mr. Cross saw the boy 12 months ago he had much photophobia, both winter and summer, and when in the light he was constantly sneezing. He found it difficult to read. Under chloroform there was found to be a dull hyperæmia of the eyeballs and two small phlyctenular swellings. The corneæ were somewhat glassy ; the pupils were small, but reacted to light and opened freely to homatropine. A few days later he saw 6/18 for a moment and J. 6. Improvement was reported after massage of the eye with calomel ointment. In November there was acute inflammation of the right eye and a fine infiltration running across the cornea. There was also a haziness of the left cornea, and a marginal spot looking like pterygium.

Mr. R. AFFLECK GREEVES showed microphotographs of sections through the conjunctival growth removed from the eye of the boy. The growth consisted almost entirely of epithelial cells, mainly prickle cells, and showed evidence of commencing malignancy.

Mr. AFFLECK GREEVES read a paper on

The Microscopical Anatomy of Syphilis of the Eye,

illustrated by microphotographs of sections taken from three cases. In the first case, one of old interstitial keratitis, he pointed to the presence of persistent though empty endothelial channels in the cornea, the remains of former blood-vessels. The second case was one of gumma of the iris, the structure of which was peculiar in that the pigment epithelium had proliferated into the inflammatory tumour and given clinically a pigmented appearance, causing to be made the erroneous diagnosis of melanosarcoma. The third case illustrated the pathological appearances of syphilitic scleritis and of a proliferative form of choroidoretinitis characterised by the presence of dense tissue between choroid and retina. This tissue, he considered, was probably produced by the proliferation of the retinal pigment epithelium.

Mr. GREEVES also read a paper by Mr. G. KOMOTO on

The Pathological Anatomy of the Retina and Choroid after the Complete and Partial Cutting-off of their Respective Blood-supplies.

It was based upon the pathological examination of an eye which was excised ten days subsequent to the cutting-off of the retinal and posterior choroidal blood-supplies by the removal of a lymphangioma from the posterior part of the orbit, along with a portion of the optic nerve. While the retina was completely necrotic posteriorly, all its layers were well preserved anteriorly. It was argued from this that the whole of the anterior part of the retina is probably almost entirely dependent on the choroidal circulation. The chromatophores of the choroid and the pigment epithelium of the retina showed peculiar changes in form, caused by their being deprived of normal blood-supply. The paper was illustrated by microphotographs.

Mr. TREACHER COLLINS read a communication on

Apparent Accommodation with Aphakia.

The case was described of a boy who had lamellar cataracts removed from his eyes when 7 years old by repeated discission operations. When he was 14 it was discovered that he was using only one pair of glasses for both distance and reading. On testing his sight it was found that he saw right with + 13, 6/6 ; left with + 13, 6/9 ; and with the same glasses in the same position on his nose, looking straight through the centre of them, he read J. 1 fluently. Any alteration in curvature of the cornea while he adapted his eye for the near point was excluded by examination with the ophthalmometer, and by the use of Batten's eyebath. Any lengthening of the antero-posterior axis of the globe was watched for by ophthalmoscopic examination. He could see just the same when the eyelids were held away from contact with the globe. When the pupils were semi-dilated with cocaine he could still read J. 1 with + 13 in ordinary daylight with the right, but only J. 2 with the left. When the pupils were fully dilated with atropine he could only read J. 10 with + 13 in ordinary daylight, but in the dark room with a strong light concentrated on the test-type he still read J. 1 better with the right eye than with the left. When examined with the pupils well dilated it was seen that in the right eye there was a membrane with a sharply defined central circular aperture in it, 3·5 mm. in diameter. In the left eye the aperture was larger and more oval in shape ; the membrane in it, moreover, did not occupy the entire pupillary area, a space being left at the circumference between it and the pupillary margin. Both pupils were regular, free from any adhesions, and acted very briskly to light. Mr. Treacher Collins considered that the evidence he had collected in connexion with this case went to show that there was not any true accommodation ; that the boy's power of seeing clearly at different distances was due to the cutting off of circles of diffusion, partly by the contraction of the pupils, but mainly by the small central openings in the membranes. He quoted several other cases which had been recorded, in which apparent accommodation was present after the removal of the lens, and advocated trying to adopt the technique in operations for soft cataract so as to produce a condition similar to that in the case here described.

Mr. TREACHER COLLINS described a case in which an

Epibulbar Epithelioma Completely Disappeared after the Application of Radium Bromide.

A man, aged 80, had a new growth about 10 mm. in diameter at the limbus in his left eye. It had formed in two years, and was gradually increasing in size. A small piece was cut off, and microscopical examination of it showed it to be an epithelial growth, which was extending into and infiltrating the episcleral areolar tissue. At the Radium Institute the patient had 10 mg. of radium bromide on a circular disc 1 cm. in diameter, unscreened ; it was held continuously over the growth for 50 minutes by a relay of assistants. After this the growth gradually disappeared. At the end of a fortnight only a thickening at the margins was left. It was now five months since the treatment, and all that could now be seen at the site was a smooth greyish scar. The way in which epibulbar epitheliomatous growths permeate the lymphatic channels and spaces in and about the eye was then demonstrated by a series of lantern slides. It was shown how, for a long time, the sclerotic resisted such permeation and the growths remained superficial, and while this stage lasted they would be eminently amenable to treatment by radium.

Dystrophies of Cornea and Glaucoma.—Primary Pneumococcal Choroiditis.—Artificial Maturation of Cataract.—Sarcoma of Socket.

Mr. GRAY CLEGG read four communications. The first was on Dystrophies of the Cornea and Glaucoma, with especial reference to a familial variety of the former. Changes in the cornea occurred which resembled those found in glaucoma, but there was no tension element. Two sisters in a family of three were shown, all affected by the disease, which probably existed in at least one other relative. Another case was related in which similar changes were present; but as there was a doubtful tension element iridectomy had been done in one eye and trephining in the other without any beneficial effect on the corneæ.

The second paper was on Primary Pneumococcal Acute Choroiditis. The disease occurred in a healthy male aged 27. It affected the right eye, which had been previously examined and found healthy. At first the appearances were considered by three oculists to be those of tubercle, consisting of two blurry yellowish-white foci at the macula. In spite of treatment an acute panophthalmitis developed, and 29 days after being first seen a Mules's operation was performed. A specimen taken at the operation showed a pure culture of the pneumococcus of Friedländer.

The third paper was on a method of Artificial Maturation of Cataract allowing of early extraction. The method was, briefly, as follows. The night prior to operation the pupil was well dilated with atropine, and paracentesis was performed with an iris knife. Massage was applied directly to the lens capsule by a smooth iris repositor, and this was followed by indirect massage by the back of a lens scoop. Atropine was again instilled. If no irritation resulted no more atropine was used after the day of operation. Often within a week the eye was perfectly quiet, the pupil returned to its ordinary size, and regained its activity. Extraction could then be resorted to, either without or with iridectomy. In this way the whole process could in many cases be gone through in three weeks to recovery.

The last paper described a case of Sarcoma of the Socket. The patient had already had his left eye removed and was wearing an artificial eye. About August, 1910, it would not keep in position owing to the presence of a pediculated growth towards the outer part of the socket. The mass was excised, but in November, 1910, it recurred. A section of the original growth raised suspicions of malignancy, and a few days later the lid margin with the conjunctiva and the whole contents of the orbit were removed. The structure, as described by Professor Walker Hall, was suggestive of perithelioma. Possibly the tumour was caused by a fine crack in the artificial eye which he had been wearing.

Mr. W. B. INGLIS POLLOCK (Glasgow) read a paper on

Dissolving Senile Cataract in the Early Stages.

In a consecutive series of 100 patients with senile cataract who were under treatment for not less than three months with alkaline lotions and dionine, fibrolysin, and iodolysin drops, 45 per cent. of the 178 eyes showed great improvement and 41 per cent. an improvement in vision; 7 per cent. remained stationary. In 8 per cent. the treatment failed to arrest the progress of the cataract. The method did not cause pain and could be persevered with over long periods. Attention should be directed to the general health, and the internal administration of an alkali was an advantage. Several patients had, he said, remained free of recurrence for a period of from three to six years.

Lieutenant-Colonel H. HERBERT, I.M.S., read a communication on

The Capsular Opacities of Morgagnian Cataract.

He showed photomicrographs of the capsule of a very long-standing cataractous lens which had passed beyond the Morgagnian stage. The capsule showed scattered white dots clinically. Under the microscope these were found to consist of spaces formed between layers of thickened capsule, and containing mainly lens débris similar to the "milk" of the cataractous lens. Reasons were given for supposing that similar changes may account for the globules or clear rings of after-cataract. And reference was made to two processes at work, singly or together, in senile cataract. The one, representing simply deficient nutrition, resulted eventually in an abnormally dry, shrunken lens. The other, apparently due largely to destruction of the lens cells lining the capsule, consisted essentially in undue admission of aqueous into the lens, and its results.

Hyperplasia with Colloid and Amyloid Degeneration of the Episcleral and Circumdural Fibrous Tissues.

Mr. GEORGE COATS recorded a case of conjunctival and orbital growth which commenced in a man aged 25 and progressed slowly during a period of observation of 17 years. Waxy, semitranslucent, nodular masses occupied the bulbar conjunctiva and overlapped the cornea. The patient's health remained unimpaired throughout. Pathologically the condition was essentially a proliferation of the deep episcleral and circumdural fibrous tissues, with a homogeneous form of degeneration which, in its more advanced manifestations, gave the staining reaction typical of amyloid disease. The vessels were similarly affected, and giant cells, lymphocytal infiltration, calcification, and ossification were present. The histology of the case was typically that of "amyloid disease of the conjunctiva," a purely local condition not associated with tubercle, syphilis, &c. The unique feature of the present case was the simultaneous involvement of the orbital tissues.

THE NATIONAL INSURANCE ACT.

The Reduction of Capitation Fees.

THE London Panel Committee, at its recent monthly meeting, gave consideration to the question of the reduction of capitation fees from 1*s.* 9*d.* to 1*s.* per quarter and decided to refuse concurrence with the proposal of the London Insurance Committee to that effect. The London Panel Committee, representing, as it does, those practitioners in the metropolitan area most intimately concerned in the matter with which it was dealing, is not likely to lack support from its constituents. It will also find sympathy accorded to it by other bodies and by individual practitioners elsewhere, who are equally concerned with the unavoidable reduction of the incomes of panel practitioners as the result of the enlistment of insured persons on their lists. At a meeting of Glasgow panel practitioners specially convened to consider the forming of a local branch of the Panel Medico-Political Union, Dr. A. Salter made special reference to what was taking place with regard to fees in London, and submitted to the meeting that precisely the same conditions would be found before long applying to medical men in Scotland. His observations on this topic and the expression of his views with regard to the policy of the Insurance Commissioners were received by his hearers with a cordiality which left no doubt as to the depth of the feeling of anxiety, not unmixed with resentment, provoked by the situation.

To return to what took place at the meeting of the London Panel Committee, the position taken up by those who discussed the resolution and substituted for it an amendment which defined that position more clearly, can hardly be treated by anyone as unreasonable, although, no doubt, the London Insurance Committee, at any rate, might, in existing circumstances, find it difficult to comply with the suggestion thus submitted to it. The recommendation made by the Panel Service Subcommittee was—

> That the Panel Committee do not concur in the proposal of the Insurance Committee to make to each practitioner on the panel during the second quarter of the medical year 1915 two payments in advance of the amount due to him, at the rate of 6*d.* for each capitation fee of 1*s.* 9*d.* credited to him in accordance with the Medical Benefit Regulations, 1913, and that the Insurance Committee be so informed.

The amendment referred to, which was moved by Dr. M. Bernstein in words suggested by the chairman, Dr. H. J. Cardale, was—

> That all words after "that" in the recommendation be deleted and the following substituted: The Panel Committee recognises that a reduction in the Medical Benefit Fund on account of insured persons who have enlisted is inevitable, and accepts it, but it does not agree to a general reduction being made from the lists of all practitioners alike, but considers that the reduction should be made strictly in accordance with the numbers removed from each list.

That reduction in the numbers of patients credited to each practitioner should follow upon the enlistment of a proportion of those patients, many of whom might never return, was inevitable. To lose income in respect of "removal" thus brought about would rank as a necessary hardship inflicted by the war, corresponding to the hardship in the form of loss of earnings endured by many of the medical man's fellow citizens. To lose income and to have the loss assessed arbitrarily and without reference to the question whether the work performed among insured patients is correspondingly diminished, stands upon quite another footing. A medical man in one district might witness the departure of 20 per cent. of his patients, and as they would be the healthiest and those giving him least trouble he would see them go with regret. He would not, however, have the same sense of injustice as would a brother practitioner deprived of 20 per cent. of his income in a district where the percentage of recruiting was very small, and in which, perhaps, on account of the presence of manufactories supplying munitions of war, the pressure of work was raising the percentage of illness among insured workers.

There is a further element in the matter also to which the attention of the London Panel Committee was called with some justice by Dr. Hogarth, who invited the Panel Committee to protest against the proposed reduction in so far as it was due to the failure of the London Insurance Committee to produce a correct register. Mr. R. J. Farman observed, in support of this point, that if the lists had been kept up to date the Insurance Committee would have been able to say at once the number of insured persons on each practitioner's list, and the number of men who had left to join the colours, thus arriving at the exact amount due to each medical man. It will be freely admitted that the amount of clerical work laid by the Insurance Acts upon the London Insurance Committee is very heavy, and that now, with the depletion of clerical staff through enlistment, its weight may be yet more heavily felt; but the criticism expressed above refers to arrears in the compilation of records and statistics which arose before the war, and medical men who themselves suffer severely if they allow the clerical work imposed upon them as members of the panel to get into arrears can hardly be expected to sympathise when the fact that the Insurance Committee has fallen behind in its office work is brought into prominence. They are rather inclined to argue that a committee should place itself or be placed by the legislature, by means with which they are not concerned, in a position to keep abreast of its routine duties, and they do not forget the difficulty and illwill which arose, markedly in London, but in other areas as well, out of delay in the allocation of patients, and the consequent creation of "unallotted funds."

Dr. Hogarth called attention also to another aspect of the case in protesting against any reduction being made at all as the result of enlistment. Medical men, he pointed out, undertook their work in normal times of peace; now they were asked to see themselves deprived temporarily of patients who were healthy and strong when the bargain for their treatment was struck, but of whom many would come back before long maimed and broken in health. They were left at present with an increased proportion of the worst of the insured, the best having gone. They were going to receive back a large number of the latter as ailing persons, and so to suffer severely as a body from the aftermath of war.

The position briefly summarised above is undoubtedly a difficult one for the medical practitioners upon the panel in London and in other areas as well. It is also by no means an easy one for the Insurance Committees, especially in the metropolis. To place the matter on a business footing, for such is the proposal of the London Panel Committee, and to pay each practitioner his agreed remuneration in respect of each patient whom he is liable to be called on to treat, would apparently in the present circumstances be a clerical operation of considerable magnitude. The urgency of the matter increases the difficulty and also the inevitable hardship to medical men, for the question has arisen over advances—that is to say, over the payment of instalments of income which is not, strictly speaking, due till the end of the year. The question was asked at the meeting of the London Panel Committee as to the position created by a refusal to agree to the proposed reduction, and the chairman frankly said that it would "hang the money up" of which the constituents of those present might be in urgent need. It is unfortunately too late now to point out that the capitation system adopted, after deliberation and discussion, in normal times of peace has not proved the best adapted for the emergency of war, and has produced a state of affairs which would not have arisen under a system of payment by fees for work done.

London Insurance Committee.

The report of the Medical Service Subcommittee laid before the London Insurance Committee at its last meeting showed that the subcommittee had only had before it in the period March 26th to April 16th seven complaints made against medical men by their patients, and that these did not even allege any serious ground of complaint. In three instances the case was met by the transfer of the patient to the list of another medical practitioner, the first medical man either asking for, or acquiescing in, the change. In another a charge of failing to provide adequate treatment was found not to have been substantiated. In two there had been irregularity in the matter of certificates of incapacity, and the medical man was recommended to be so informed, and in the seventh, the practitioner having been informed that he was not entitled to a fee which he had been paid, had returned it to the patient, and the matter was allowed to rest there. In this last instance the question was whether there had been a miscarriage on the part of the complainant, for which the medical man on the panel should have given his attendance as for an illness, or a birth, for which he would have been entitled to make a charge. The conditions necessary to constitute a confinement as contemplated by Clause 2 (1) of the practitioner's agreement are the issue of a living child, or labour after 28 weeks' pregnancy whether the issue be alive or dead. The complainant alleged four months' pregnancy and a miscarriage. The practitioner was of the opinion that his patient had been pregnant for six months and thought himself entitled to charge, but the subcommittee pointed out that he was wrong as to this upon his own showing, as there had not been the birth of a living child. In another case in which a medical man was concerned he was the complainant and secured the transfer of one of his patients to another practitioner's list.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

MEETING OF COMITIA.

A COMITIA was held on April 29th, Dr. FREDERICK TAYLOR, the President, being in the chair.

The following candidates having passed the required examination were admitted Members of the College:—Cyril Dudley Kely Corbett, M.D. Oxon., L.R.C.P., and Joseph Strickland Goodall, M.B. Lond.

Licences to practise physic were granted to 101 candidates who had passed the necessary examinations.

The following Members were elected Fellows of the College:—Archibald Donald, M.D. Edin. (Manchester); George Gavin Morrice, M.D. Cantab. (Weymouth); Thomas Beattie, M.D. Durh. (Newcastle-on-Tyne); Noel Dean Bardswell, M.D. Edin. (Midhurst, Sussex); Frank Cecil Eve, M.D. Cantab. (Hull); John Hay, M.D. Vict. (Liverpool); George William Watson, M.D. Lond. (Leeds); Reginald Charles Jewesbury, M.D. Oxon.; Edwin Greaves Fearnsides, M.D. Cantab.; Thomas Renton Elliott, M.D. Cantab.; and John George Adami, M.D. Cantab. (Montreal, Canada). Grafton Elliot Smith, M.D. Sydney, F.R.S. (Manchester), was also elected a Fellow of the College under By-law LXXI.

The President was re-elected a representative of the College on the Senate of the University of London.

Two communications were received from the Secretary of the Royal College of Surgeons of England, dated March 12th and April 9th, 1915, respectively, reporting proceedings of the Council of that College on March 8th and April 8th.

A report from the Committee of Management was received and adopted, dated March 8th, recommending that the University of Illinois be added to the list of foreign universities recognised by the Examining Board in England; another report, dated March 15th, was also received and adopted recommending that the following Portuguese Universities be added to the list: University of Coimbra, University of Lisbon, and University of Oporto.

Another report from the Committee of Management, dated April 21st, referred to a letter received from the Dean of St. Bartholomew's Hospital Medical School suggesting that during the war it might be possible to shorten the curriculum for medical students; and a letter had also been received from the Director-General of the Army Medical Service expressing the hope that the Royal Colleges would give the matter their most earnest consideration. The Committee of Management were of opinion that it was not desirable that the two important requirements of the regulations—(1) a minimum curriculum of 57 months, and (2) a minimum period of clinical study during two winter and two summer sessions after passing in anatomy and physiology—should be relaxed at the present time. The committee desired to point out, however, that under the regulations of the board they had power to grant exceptions to the regulations and that they had already exercised this power in cases where the two important principles above referred to had not been involved. They were prepared to antedate the commencement of the curriculum in cases where students had pursued medical or scientific study before passing the Preliminary Examination, or before entrance at a medical school, and they believed, from inquiries which had been made, that this procedure would enable the majority of the students referred to by the Dean in his letter to enter for the Final Examination three months earlier than would otherwise have been possible, and yet with a full curriculum of 57 months. The report was adopted.

After some further formal business the PRESIDENT dissolved the Comitia.

ASYLUM REPORTS.

Roxburgh, Berwick, and Selkirk District Board of Lunacy (*Annual Report for the Year ending May 15th, 1914*).—The total number of patients under treatment during the year was 398, the average daily number resident being 321·1. The patients admitted during the year numbered 71, and of these 15 had been previously under treatment in this asylum. Hereditary predisposition to mental disorder was ascertained to exist in 25 cases, and more than half of the cases suffered from some form or other of bodily disease for which medical treatment was required. In 18·3 per cent. of the total admissions the age was over 70 years. The discharges numbered 40, with a recovery rate of 33·8 per cent., calculated on the total number of admissions. The rate of mortality calculated on the average number resident was 7·6 per cent. Pulmonary tuberculosis was ascertained to be present in an active form in 20 per cent. of the deaths.

East Sussex County Asylum, Hellingly (*Annual Report for the Year ending March 31st, 1914*).—The total number of cases under treatment during the year 1913 was 1374, the average daily number resident being 1122. There were 228 direct admissions. With regard to these, the most noticeable features were the diminution in the number of those suffering from what may be called the more obvious forms of insanity—i.e., acute mania and acute melancholia, and the increase in the number of patients suffering from dementia præcox (primary dementia) and those forms of insanity due to toxic causes, such as confusional insanity, acute and chronic hallucinatory insanity; there was also an increase in the number of patients suffering from delusional insanity, more especially the paranoid form. It would appear that the prognosis so far as complete recovery is concerned is in many of these latter forms of insanity not very favourable, and, moreover, that the type of insanity in this district seems to be gradually changing. The discharges numbered 141, with a recovery rate on the direct admissions of 41·66 per cent. A considerable proportion of patients were sent out at first "on trial," and the After-Care Association has recently decided to assist these patients in the same way that they do those discharged "recovered." There were 102 deaths, making a rate of 9·09 per cent. on the average daily number resident. Tuberculosis was the cause of death in 10·7 per cent. of the total number. The causes of death were verified by post-mortem examination in 74 per cent. The number of post-mortem examinations has considerably decreased since the Commissioners expressed the opinion that before any examination is made the consent of the friends must be obtained after the death of the patient.

Govan District Asylum, Hawkhead, Paisley (*Annual Report for the Year ending May 14th, 1914*).—The total number of cases under treatment during the year was 956, the daily average number resident being 654·3. The total number of admissions was 309, of whom 261 were first admissions and 48 were readmissions. There were 176 patients discharged, with a recovery rate calculated on the total admissions of 27·5 per cent. This is a low recovery rate, but it is accounted for to a large extent by the fact that the Govan parish authorities have to take charge, in the first instance, of many patients who fall ill within their district, although they have not a settlement in the parish (deports from Canada and America included). Many of these are afterwards transferred to the asylums of their own districts before recovery has taken place. The deaths were at the rate of 19·1 per cent. of the average daily number resident. Among the factors found to be associated with the outbreak of the mental disorders there stand pre-eminent: (1) Physical debility and disease; and (2) alcoholic excess. Of the patients admitted, over 78 per cent. were in an unsatisfactory state of health. In a considerable proportion of cases the patients on admission were suffering from the terminal stages of bodily diseases, and this is reflected in a high death-rate and a low recovery rate. Alcoholic excess was present as the predominant causative agent in no less than 25·2 per cent. of the men and 7·6 per cent. of the women. As a rule, alcoholic excess was found to be associated with a reduced physical condition or actual bodily disease. In 28 per cent. of the male alcoholics, however, the general physical condition was fair, and no evidence or history of previous bodily disease was obtained. The figures given above relate exclusively to patients admitted for the first time. When this is considered in conjunction with the fact that a considerable proportion of individuals suffering from acute forms of alcoholic mental disorder (e.g., delirium tremens) are not now sent to the asylum, but are treated in the observation wards of the parish hospital, it can hardly be denied that excessive drinking habits are largely responsible for the prevalence of mental unsoundness in the community.

Stirling District Lunacy Board for the Counties of Stirling, Dumbarton, Linlithgow, and Clackmannan (*Annual Report for the Year ending May 15th, 1914*).—The total number of cases under treatment during the year was 1073, the average number resident being 794. The total number of admissions amounted to 294, which is the largest number during any year since the opening of the asylum. Fifty-eight of those admitted had been under treatment before. Alcoholic excess was found to be the cause in 75 cases, or 25 per cent. of those admitted. In 69 cases, or 23 per cent., an inherited predisposition was admitted, and in 106 cases the mental breakdown had occurred at one of the critical periods of life. There were 182 patients discharged, with a recovery rate calculated on the total admissions of 39·4 per cent. The deaths during the year numbered 105, making a death-rate, calculated on the average number resident, of 13·2 per cent. This is the largest death-rate in any one year since the asylum was opened, and is entirely due to the large number of cases admitted in a weak and exhausted condition.

Lanark District Asylum, Hartwood (*Annual Report for the Year ending May 31st, 1914*).—The average daily number resident in the asylum during the year was 1001, and the total number of admissions was 220. With regard to the causes of insanity, intemperance appeared in 26 cases, heredity in 15, epilepsy in 15, and senility in 25. The number of cases discharged was 106, and there were 65 deaths. The recovery rate was 37 per cent., reckoned on the certified admissions, and the death-rate 6½ per cent. on the average number resident. This is the lowest death-rate since 1903. Of the 65 deaths, 10 were due to general paralysis of the insane, 13 to morbus cordis, and 12 to phthisis pulmonalis. Great attention continues to be paid to the industrial employment of the patients. The levelling of the site of the new hospital was carried out wholly by the labour of the patients.

REPORT ON THE CONTAGIOUS DISEASES OF ANIMALS.[1]

THE report by Mr. A. W. Anstruther, presented to both Houses of Parliament by command of His Majesty, gives a good idea of the work the Board of Agriculture and Fisheries is doing in regard to the prevention, eradication, and control of the contagious diseases of animals. It marks an advance on any previous report yet issued, from the point of view both of the more exact methods used against disease in the light of experience gained in past years and of the pliability of scientific procedure in dealing with a scourge that in this country has baffled all preventive and curative measures for many years and has resulted in a great and largely unproductive expenditure of public money. We refer to sheep scab and swine fever.

An assurance that in a number of cases the ophthalmic test for glanders had been applied would have further rounded off some of the scientific features of this report. On the whole, however, it may be said that the record is a progressive and gratifying one, and if military operations had not checked and hindered the work of the Board it would have been still more gratifying. The war has necessitated the local authorities and their police being temporarily relieved of some of their duties; and some of the Orders, notably those against tuberculosis and mange, have been for a time suspended, whilst others have been somewhat modified.

Foot and Mouth Disease.—Tuberculosis.

Foot and mouth disease has caused the authorities much trouble and anxiety, especially on the administrative side, and since Jan. 31st, 1914, it has needed almost constant attention. Here the prompt measures taken against 29 suspected cases and 27 confirmed outbreaks have been quite effective. The fact that a good position has been maintained in regard to this disease, notwithstanding military operations and the consequent disorganisation of control methods, is very praiseworthy, whilst the value of nipping outbreaks of the epizootic in the bud cannot be over-estimated. Failure to secure early control of the disease is invariably disastrous in its consequences, as witness the outbreaks in America during the late months of last year. Preventive measures included a special order in regard to the landing of animals from Ireland, and in connexion with this it is to be noted that the report mentions that "the arrangements for the detention of animals under veterinary supervision at the port of landing have undoubtedly been useful from the point of view of reducing the risk of the spread of the disease in Great Britain as well as beneficial to the animals themselves."

Advance has been made in regard to tuberculosis, and improvements in the new Order operative from July 1st to August 6th (the date of the suspension) include the obligation of notification of those animals suffering from a chronic cough and showing definite clinical signs of tuberculosis, fixing the basis of animal valuation at the market rate, and allowing a refund from the Imperial Exchequer to the local authorities of three-fourths of the gross compensation (i.e., without any deduction in respect of the proceeds of the sale of carcasses) computed on the market value of the animal as ascertained by the valuer. The new Tuberculosis Order remains in abeyance until Oct. 1st, 1915. The notifications in July were 766, as compared with a monthly average of 568 animals under a 14 months application of the old Order. It is assumed, therefore, that there will be a marked increase in the subjects to be dealt with when the Order is revived on the same date that the Milk and Dairies Acts come into force—viz., Oct. 1st, 1915.

Swine Fever.

Gloomy to read is the statement that since 1896 the total number of cases of swine fever in Great Britain has never been higher than in 1914, and 4356 outbreaks have been confirmed. The increase in cases is ascribed chiefly to virulent outbreaks in Suffolk, Essex, and West Sussex, to the pressure on the inspectorate indirectly due to the war, and to the exceptional conditions existing in the eastern and southern counties owing to military operations. The comparatively mild winter and the great amount of wet and humid weather, combined with the increase of pig-breeding operations, probably also had their influence in augmenting the number of outbreaks. The total increase of swine in Great Britain, at the count taken in June, was 400,394, a very gratifying advance from both an economic and a zootechnical point of view.

We now come to one of the most important and valuable points in the report—important because a commencement has been made with a method of dealing with the disease long since adopted in other countries, and valuable because we shall soon know what a changed plan of action is likely to accomplish in this country. We have travelled too long on the old well-trodden way without getting any nearer to our journey's end.

On Jan. 26th, 1914, the Swine Fever Committee reported rather adversely on hitherto known methods of artificial immunisation against swine fever, but it indicated that existing modes of inoculation might be serviceably employed in controlling the disease, and it advised further experimenting to discover a trustworthy form of vaccination. A Departmental Committee recommended field observations upon selected premises with regard to serum treatment. These have been undertaken in a district round Colchester, where a virulent form of the disease was present, and the committee will soon be in a position to make a final report on the value of the method. Of course, any judgment to be useful presupposes that adequate administrative and hygienic measures will accompany the serum and virus treatment. American and German authorities assert that the double method of treatment by serum and virus blood bestows immunity for life.

Sheep Scab, Anthrax, Glanders, &c.

The double dipping Sheep Order is the result of lessons learnt from experience, and it is rather surprising that it has not been adopted earlier. Sheep scab is now to be seriously combated, and we may look to its decrease in the future. It is a pity the operation of the Order has had to be suspended, but it will be reimposed at an early date.

The outbreaks of anthrax were 128 more than in 1913. There appears to be an intimate connexion between them and the importation and use of artificial feeding-stuffs. These are legion and multiply every month. Several outbreaks on the continent have been traced to infected fish meal. We shall never improve on natural methods of feeding by artificial ones, but labour on the land never seems so productive as manufacturing operations, at any rate it is not so well organised. The perspiration of the body seems rapidly giving way to the sweat of the brow.

Glanders shows a steady decline, there being a drop of 65 in the number of outbreaks as compared with last year. A healthy result and very creditable to the Board. The trade in Russian ponies, which previously caused some outbreaks of glanders, has been suspended.

Parasitic mange shows a decrease of 279 outbreaks, but the Order is now suspended, which is unfortunate. We should have liked to read the opinion of the Board as to the reason why the disease is far and away most prevalent in London, Lancashire, and the West Riding of Yorkshire.

The dogs imported into Great Britain numbered 1250, which exceeds all previous records. They were all subjected to the Quarantine Order.

The trade in old horses materially improved under veterinary supervision up to August 3rd, 1914, when the Royal Proclamation with respect to the export of animals put an end to it.

ROYAL COLLEGE OF SURGEONS IN IRELAND AND THE CASTLE HOSPITAL.—The students of the Royal College of Surgeons, with the aid of Licentiates and Fellows, are endeavouring to maintain one ward in the Dublin Castle Red Cross Hospital. A concert in aid of this undertaking was held recently in the hall of the College, and a satisfactory sum was realised. A chief feature of the concert was a prologue written for the occasion by Mr. Oliver Gogarty, F.R.C.S. Irel.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been appointed Surgeons for temporary service in His Majesty's Fleet:—Dated April 23rd: Jack Rupert Law Willis and William Hunter Kay. Dated April 24th: John Cadzow Sinclair.

The following appointments have been notified:—Temporary Surgeons: E. F. Fox to the *Victory*, additional, for Engineering Unit, R.N. Division, Deal; H. G. Moser to the *Neptune*; J. R. L. Willis to the *Vivid*, additional, for disposal; W. S. Lynd, J. S. Kennedy, and D. S. Falconer to the *Victory*. additional, for Haslar Hospital; J. C. Sinclair and W. H. Kay to the *Pembroke*, additional, for disposal; and W. E. Goss to the *Vivid*, additional, for disposal.

ROYAL NAVAL VOLUNTEER RESERVE.

Surgeon Charles Devereux Marshall has been promoted to the rank of Staff Surgeon (dated March 31st).

ROYAL ARMY MEDICAL CORPS.

Major Arthur W. Mayo Robson, C.V.O., to be temporary Lieutenant-Colonel (dated March 1st). Alexander George Pemberton Gipps, late Fleet-Surgeon, Royal Navy, to be temporary Major (dated March 18th, 1915).

The undermentioned to be temporary Majors: William Pearson (dated April 7th) and James Laidlaw Maxwell (dated April 8th).

The undermentioned temporary Lieutenants to be temporary Captains:—Dated May 5th: Francis Hernaman-Johnson, late Surgeon, Royal Navy; Ernest W. Witham, late Surgeon-Captain, Assam Valley Light Horse. Dated May 4th: Albert T. Duka, D.S.O.

The undermentioned to be temporary Captains:—Dated April 7th: John Heatly Spencer, Charles Edward Murphy, Gerald Theodore Sylvester Sichel. Dated April 9th: Hector Munroe. Dated April 14th: John Aldington Gibb and Sir Vincent Nash.

The undermentioned to be temporary Lieutenants:—Dated Feb. 27th: George Norman Lorimer and Cletus McShane. Dated March 9th: Matthew Edward Robinson, Hugh Noel Murray Puckle, Reginald Morley Clarke, John William Farrar, Alan Thomas Roberts, George Dibbs King Waldron, James Ian Munro Jamieson, William Eric Giblin, William Angwin Edwards, Donald Francis Finlay, Leslie John Jarvis Nye, Lionel Braim Daly, Francis Esmond Keane, George Alexander Birnie, and Oswald Barton. Dated March 22nd: Henry Reynolds Brown. Dated March 23rd: William Arthur Rees. Dated March 25th: Herbert Ernest Clutterbuck and Sydney Williams. Dated March 27th: Thomas Paterson Noble. Dated March 30th: Theodore Henry Whittington. Dated March 31st: Ernest Harold Drinkwater. Dated April 1st: Bernard Hugh Stanley Aylward and Ernest Augustus Aylward. Dated April 7th: David Riddell, Ernest Emrys Isaac, Cuthbert John Nicholson, Frederick Talbot Driffield Clindening, Ninian McIntire Falkiner, Reginald Torriano Cooke, James Wodderspoon Bennett, Adolphe Abraham, Max Hershel Edward Richard Montesole, Hubert Vere Leigh, Roger Llewellyn Williams, John William Heekes, Thomas Dinnen Jago, Cecil Hutchinson Hopwood, William Frederick Abbott, Ernest Wardlaw Milne, Arthur James Henry Boyton, Clarence Brian Dobell, Frederick Aylmer Hort, Ian Campbell, Harry Crichton, Thomas Fearnhead, Charles Launder Chalk, Frank Louis Underwood, Everard M. le Poer Power, Martin Remers, George Burrows Brown, Duncan MacNab Callender, Lanchlan Rose, John Brown, William Douglas Knocker, John Murdo MacPhail, George Aubrey Jelly, William Kirk, Charles Fortescue Pricham, Robert Michael Forde, Thomas Paul Gray, John Ross Hoare Ross, Anthony Ashley Cooper, John Musgrave Twentyman, Ernest Morley Rooke, Charles Augustus Farrell, Marshall Hall, Alfred Ernest Carsberg, Reginald Wilton Trevor Clampett, George Howard Strettell Letchworth, Francis Sidney Mitchell, Claude Ernest Willington Wilmot, Edward Chapman Wallace, Robert Morrison Clarke, Robert Maxwell Chance, Harold Arthur Upward, Henry Herbert Clarke, and George Min Adam. Dated April 8th: Ernest Villiers Hunter, John Black Mason, Cuthbert John Butler, Benjamin Sweeter, Henry Hope Knox Sparrow, William Leggett, John Thomas Hurst, Benjamin Banks Ferrar, Robert Buchanan, William Wilfred Banham, John Henry Blakeney, Robert Scott Dewar, Cyril Herbert Thomas Ilott, George Maxwell Elliott, James Arthur Richard Lee, Alexander Charles Profeit, Robert Alexander Garden Whiting, Fife Slater, Isaac Alexander Davidson, and Norman Grenville Walsh Davidson. Dated April 9th: Robert Mitchell MacKay, Stanley James Annear Beale, Edward Alban Evans, William Macdonald, and Thomas Arthur Fuller. Dated April 10th: Ralph Christopher Fuller, Frederick Michael Kirwan, William Edmund Cooke, William Henry Hooton, George Frederick Holt, Frank Jerome Dunne, Alexander John Campbell, Finlay Stewart Campbell, Andrew Adams Rutherford, David McKinlay Reid, Henry Harold Robinson, Gerald Irving Moriarty. Hugh Tennant Prince, Augustus William Tabuteau, Cyril William Jenner, John Harold Mason, and William Walter Dickson. Dated April 12th: John Stephen Herbert Lewis, Redcliffe Nathan Salaman, John Travers McConkey, Charles Alfred Whiting Pope, Wallace Tynemouth Hedley, Edward Henry Pollock Brunton. Thomas Strain, Andrew Graham Ritchin Ritchie, George Albert Simpson, Daniel Cowin, and William Southmead Langworthy. Dated April 13th: Robert Richards, William Christopher Gavin, John Milnes Pooley, and Edmund William Lynch. Dated April 14th: William Alister Alexander, Percy Ellwand Middleton, Wilfred Edgcumbe Burrows, Walter Salisbury. Herbert John Hickin, Frank Brickwell, Alexander Elmslie Campbell, Charles James Armstrong-Dash, Ernest George Klumpp, Victor Harold Mason, Ian Macfarlane, and Henry Edward O'Brien,

Temporary Lieutenant Charles Gibson, having ceased duty with the British Red Cross Hospital, Netley, relinquishes his commission (dated April 19th).

Temporary Lieutenant Raymond J. Jones relinquishes his commission (dated Feb. 28th), as does also Temporary Lieutenant Edward M. Hime (dated April 27th).

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officer:—Temporary Lieutenant to be Temporary Captain: Thomas Henry Bishop (dated April 18th.

The promotion of Major William Reith John Scroggie is antedated from Jan. 29th, 1914, to July 29th, 1913.

The King has approved of the retirement of Lieutenant-Colonel Robert Henry Elliot.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned ex-Cadets of the Officers Training Corps to be Lieutenants (on probation): Austin Basil Clarke, James Gordon Wilson, and Alfred Thomas Logan.

Captain Philip N. Button resigns his commission on appointment as temporary Surgeon, Royal Navy.

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd East Lancashire Field Ambulance: Lieutenant William J. Reid to be Captain, and to remain seconded.

Highland Mounted Brigade Field Ambulance: George Munro McLeod to be Lieutenant.

1st East Anglian Field Ambulance: Lieutenant Gilbert C. Gray to be temporary Captain.

1st Home Counties Field Ambulance: Henry George Lynwood Allford (late Captain, Territorial Force Reserve, General List) to be Captain (temporary).

1st East Lancashire Field Ambulance: Captain Charles Roberts is restored to the establishment.

5th London Field Ambulance: Captain John H. Dixon, from the London Mounted Brigade Field Ambulance, to be Captain.

1st North Midland Field Ambulance: Lieutenant Kenneth B. Clarke, from the Eastern Mounted Brigade Field Ambulance, to be Lieutenant.

2nd Northumbrian Field Ambulance: James Gill Hill to be Lieutenant.

4th London General Hospital: Francis Whittaker Tunnicliffe to be Captain, whose services will be available on mobilisation.

1st Northern General Hospital: The undermentioned to be Lieutenants: Sydney Havelock, Charles Henry Keay (late Cadet Lance-Corporal, Durham University Contingent, Senior Division, Officers Training Corps).

5th Northern General Hospital: Captain Bernard Stracey, from the North Midland Casualty Clearing Station, to be Captain, whose services will be available on mobilisation.

2nd Scottish General Hospital: James Miller to be Captain, whose services will be available on mobilisation.

2nd Western General Hospital: Captain Wilson H. P. Hey is seconded for service with No. 18 Field Ambulance, Royal Army Medical Corps, Special Reserve. Captain Charles Roberts, from 1st East Lancashire Field Ambulance, to be Captain.

1st London (City of London) Sanitary Company: Daniel McPherson Taylor to be Lieutenant.

Lowland Casualty Clearing Station: Lieutenant Geoffrey B. Fleming to be Captain.

South Midland Casualty Clearing Station: Major Peverel S. Hichens, from Attached to Units other than Medical Units, to be Major.

Northumbrian Casualty Clearing Station: Harold Muir Evans (late Surgeon-Captain, 1st Norfolk (Volunteers) Artillery) to be Major (temporary). Second Lieutenant Colin Mearns, from the Durham Light Infantry, to be Lieutenant.

West Riding Casualty Clearing Station: Peter McEwan to be Lieutenant.

London Mounted Brigade Field Ambulance: Captain William B. Thomas to be temporary Major.

3rd East Anglian Field Ambulance: John Norman Robins to be Lieutenant.

3rd Lowland Field Ambulance: Lieutenant Archibald C. McMaster to be Captain.

2nd Eastern General Hospital: Harold Harris Elborough Scatliff (late Captain, Sussex Royal Garrison Artillery) to be Captain, whose services will be available on mobilisation (temporary).

Attached to Units other than Medical Units.—Lieutenant Louis B. Stringer resigns his commission.

Indian Medical Service Commissions.

An examination for not less than 10 Commissions in His Majesty's Indian Medical Service will be held in London on July 12th, 1915, and the five following days. Particulars and forms of application can be obtained from the Military Secretary, India Office, London, S.W.

Journal of the Royal Army Medical Corps.

The current number of this journal, dated January, gives first place to a preliminary note on the treatment of anaerobe-infected wounds with lactic acid. While engaged in the study of the flora of septic wounds it occurred to Major L. W. Harrison, D.S.O., the author of the note, that since anaerobes of the gas-brand and malignant œdema series degenerate, fail to spore, and do not liberate toxin in a distinctly acid culture medium, wounds might be treated in a manner which would make the discharge distinctly acid to litmus. Two severe cases are described in which wounds were treated with lactic acid, and, although one patient died, Major Harrison believes that the activity of the anaerobes was hampered more than by other modes of treatment. He has no evidence, however, that lactic acid is of any use against cocci. In a joint paper by Major E. A. Bourke, Lieutenant Idris D. Evans, and Lieutenant Sydney Rowlands on Preliminary Observations on the Use of an Autogenous Living Vaccine in the Treatment of Enteric Fever the authors describe six cases in which the employment of autogenous living vaccine produced satisfactory results, and the writers hope that the method of treatment will be given a more extensive trial. Major M. F. Foulds has an interesting note on the use of tincture of iodine in the prevention of venereal diseases. Among other contents of the journal is the description of the conversion of a railway porter's truck into a carrying chair for the wounded and of a form of folding trestle for the conversion of a stretcher into an improvised bed, both useful devices.

VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING MARCH, 1915.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 6·6 per 1000 of the population, estimated at 4,516,612 persons; in the three preceding months the rates were 9·2, 7·4, and 7·4 per 1000 respectively. The lowest rates last month were recorded in Kensington, Chelsea, Hampstead, Poplar, and Bermondsey; and the highest rates in Bethnal Green, Holborn, Deptford, Greenwich, and Woolwich. Two cases of small-pox, both belonging to Greenwich, were notified during the month. The prevalence of scarlet fever showed a marked decline from that recorded in other recent months; this disease was proportionally most prevalent in Hammersmith, Holborn, Bethnal Green, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 2514 scarlet fever patients at the end of the month, against 4431, 3609, and 2989 at the end of the three preceding months; the weekly admissions averaged 278, against 445, 317, and 324 in the three preceding months. Diphtheria was less prevalent than in the previous month; among the several boroughs the greatest proportional prevalence was recorded in Holborn, the City of London, Bethnal Green, Stepney, and Deptford. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1663, 1621, and 1562 at the end of the three preceding months, had further declined to 1362 at the end of the month the weekly admissions averaged 142, against 177, 160 ,and 172 in the three preceding months. Enteric fever was very much less prevalent than it had been in the preceding month; the greatest proportional prevalence was recorded in Southwark, Bermondsey, Deptford, and Woolwich. The Metropolitan Asylums Hospitals contained 46 enteric fever patients at the end of the month, against 68, 50, and 64 at the end of the three preceding months; the weekly admissions averaged 8, against 10, 6, and 13 in the three preceding months. Erysipelas was proportionally most prevalent in Hackney, Shoreditch, Bethnal Green, Southwark, and Woolwich. The 21 cases of puerperal fever notified during the month included 2 each in Islington, Hackney, Poplar, Bermondsey, Wandsworth, and Camberwell. The cases of cerebro-spinal meningitis numbered 154, this disease being proportionally most prevalent in Hammersmith, Shoreditch, Greenwich, and Woolwich. The 4 cases of poliomyelitis included 2 in Islington and 2 in Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations of the several boroughs. During the five weeks ending April 3rd the deaths of 9181 London residents were registered, equal to an annual rate of 21·2 per 1000; in the three preceding months the rates were 16·7, 19·6, and 20·7 per 1000. The death-rates during the month ranged from 15·5 in Lewisham, 16·8 in Hampstead, 17·7 in Fulham, 18·1 in Wandsworth, and 18·3 in Hackney, to 25·1 in Finsbury, 25·2 in Chelsea, 26·1 in the City of London, 26·5 in Southwark, and 29·1 in Bermondsey. The 9181 deaths from all causes included 1073 which were referred to the principal infectious diseases; of these, 666 resulted from measles, 38 from scarlet fever, 71 from diphtheria, 188 from whooping-cough, 12 from enteric fever, and 98 from diarrhœa and enteritis among children under 2 years of age. The lowest death-rates from these diseases in the aggregate were recorded in Chelsea, Hackney, the City of London, Shoreditch, and Lewisham; and the highest rates in Paddington, Kensington, Bethnal Green, Bermondsey, and Battersea. The 666 deaths from measles were more than double the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Paddington, Kensington, Fulham, Bethnal Green, Bermondsey, and Battersea. The 38 fatal cases of scarlet fever were 17 in excess of the corrected average number, and included 4 in Lambeth and 3 each in Hammersmith, St. Pancras, Stepney, Battersea, and Wandsworth. The 71 deaths from diphtheria were 19 above the corrected average number; this disease showed the greatest proportional mortality in Paddington, St. Pancras, Hackney, Holborn, Bethnal Green, Stepney, Poplar, and Deptford. The 188 deaths from whooping-cough exceeded the corrected average by 22; the highest death-rates from this disease were recorded in Holborn, Finsbury, Bethnal Green, Poplar, Bermondsey, Battersea, Deptford, and Greenwich. The 12 deaths referred to enteric fever were 4 above the corrected average, and included 2 in Paddington, 2 in Poplar, and 2 in Deptford. The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in Holborn, Bethnal Green, Poplar, Southwark, Bermondsey, Greenwich, and Woolwich. In conclusion, it may be stated that the aggregate mortality in London during the month from the principal infectious diseases, excluding diarrhœa, was nearly 79 per cent. above the average.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8952 births and 6022 deaths were registered during the week ended Saturday, May 1st. The annual rate of mortality in these towns, which had been 19·9, 19·0, and 17·4 per 1000 in the three preceding weeks, further fell in the week under notice to 17·3 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of last year. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 18·4, against a corresponding rate of 19·6 per 1000 in London. Among the several towns the death-rate last week ranged from 8·4 in Blackpool, 8·9 in Carlisle, 9·2 in Norwich, 9·3 in Southend-on-Sea, and 10·2 in Enfield to 23·8 in St. Helens, 23·9 in Sunderland, 24·0 in West Bromwich, 25·6 in Wigan, and 30·5 in Middlesbrough.

The 6022 deaths from all causes were 41 fewer than the number in the previous week, and included 711 which were referred to the principal epidemic diseases, against numbers declining from 826 to 689 in the four preceding weeks. Of these 711 deaths, 392 resulted from measles, 142 from whooping-cough, 73 from infantile diarrhœal diseases, 56 from diphtheria, 34 from scarlet fever, 12 from enteric fever, and 2 from small-pox. The mean annual death-rate from these diseases was equal to 2·0 per 1000, and coincided with that recorded in the previous week. The deaths attributed to measles, which had declined from 495 to 389 in the four preceding weeks

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING MARCH, 1915.

* Including membranous croup. † The death-rates are corrected for variations in sex and age constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

slightly rose to 392 last week, and caused the highest annual death-rates of 3·4 in Sunderland, 3·7 in Edmonton, 3·8 in Wolverhampton, 4·0 in Barrow-in-Furness, 4·1 in Middlesbrough, 4·3 in Merthyr Tydfil, 5·0 in Walsall, 5·3 in West Bromwich, and 6·9 in Northampton. The deaths referred to whooping-cough, which had been 167, 151, and 149 in the three preceding weeks, further fell to 142 last week; the highest recorded death-rates from this disease were 1·3 in Southampton, 1·5 in Walthamstow, 1·6 in Middlesbrough, 1·8 in Great Yarmouth, 2·0 in Wakefield, 2·4 in Rotherham, 2·6 in St. Helens, 3·5 in Stockton-on-Tees, and 5·7 in Wigan. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 67, 63, and 65 in the three preceding weeks, further rose to 73 last week, and included 17 in London, and 4 each in Leicester and Middlesbrough. The deaths attributed to diphtheria, which had been 49, 55, and 49 in the three preceding weeks, rose to 56 last week, of which 12 were registered in London, 5 in Stoke-on-Trent, 3 each in Leyton, Birmingham, and Bradford. The deaths referred to scarlet fever, which had increased from 16 to 29 in the four preceding weeks, further rose to 34 last week, and included 9 in London, 3 each in Manchester and Sheffield, and 2 each in Willesden, Stoke-on-Trent, Birmingham, Bradford, and Gateshead. The fatal cases of enteric fever, which had been 7, 11, and 8 in the three preceding weeks, rose to 12 last week, and included 3 in Salford and 2 each in London, Stoke-on-Trent, and Leeds. The 2 deaths from small-pox belonged to Bristol.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5036 to 2369 in the 22 preceding weeks, had risen to 2377 on Saturday last; 316 new cases were admitted during the week, against 275, 263, and 259 in the three preceding weeks. These hospitals also contained on Saturday last 1230 cases of diphtheria, 274 of measles, 62 of enteric fever, and 16 of whooping-cough, but not one of small-pox. The 1575 deaths from all causes in London were 44 fewer than in the previous week, and corresponded to an annual death-rate of 18·2 per 1000. The deaths referred to diseases of the respiratory system, which had been 466, 469, and 392 in the three preceding weeks, further fell to 347 in the week under notice, but were 162 in excess of the number in the corresponding week of last year. The deaths from influenza numbered 30, against 46, 39, and 27 in the two preceding weeks.

Of the 6022 deaths from all causes in the 96 towns 215 resulted from different forms of violence and 408 were the subject of coroners' inquests, while 1703 occurred in public institutions. The causes of 35, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in 13 of its 14 suburban districts, in Leeds, Bristol, Bradford, Hull, Newcastle-on-Tyne, and in 56 other smaller towns. Of the 35 uncertified causes of death, 5 were registered in Birmingham, 4 in Liverpool, 3 each in West Bromwich and Gateshead, and 2 each in Stoke-on-Trent, Preston, and Sheffield.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1285 births and 909 deaths were registered during the week ended Saturday, May 1st. The annual rate of mortality in these towns, which had been 20·8, 20·9, and 18·5 per 1000 in the three preceding weeks, rose to 20·2 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 20·1, against a corresponding rate of 18·4 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 12·8 in Kirkcaldy, 12·9 in Clydebank, and 14·9 in Hamilton, to 21·3 in Coatbridge, 23·3 in Leith, and 25·0 in Dundee.

The 909 deaths from all causes were 75 in excess of the number in the previous week, and included 150 which were referred to the principal epidemic diseases, against numbers declining from 181 to 128 in the four preceding weeks. Of these 150 deaths, 82 resulted from whooping-cough, 36 from measles, 12 from diphtheria, 11 from scarlet fever, and 9 from infantile diarrhœal diseases, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 3·3, against a corresponding rate of 2·0 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 75, 90, and 75 in the three preceding weeks, rose to 82 last week, and included 42 in Glasgow, 14 in Dundee, 8 in Edinburgh, and 4 each in Paisley and Greenock. The deaths referred to measles, which had been 41, 19, and 26 in the three preceding weeks, further rose to 36 last week, of which 25 were registered in Glasgow and 9 in Aberdeen. The fatal cases of diphtheria, which had been 11, 7, and 6 in the three preceding weeks, rose to 12 last week, and included 2 each in Glasgow, Leith, and Motherwell. The deaths attributed to scarlet fever, which had been 6, 7, and 7 in the three preceding weeks, further rose to 11 last week, of which 3 occurred in Glasgow, and 2 each in Leith and Clydebank. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 18, 10, and 12 in the three preceding weeks, fell to 9 last week, and included 2 in Leith and 2 in Kilmarnock.

The deaths referred to diseases of the respiratory system, which had been 182, 178, and 145 in the three preceding weeks, rose to 153 in the week under notice, and were 63 in excess of the number in the corresponding week of last year. The deaths attributed to violence numbered 25, against 21 and 30 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,212,380 persons at the middle of this year, 658 births and 444 deaths were registered during the week ended Saturday, May 1st. The annual rate of mortality in these towns, which had been 23·8, 22·1, and 22·4 per 1000 in the three preceding weeks, fell to 19·1 per 1000 in the week under notice. During the first four weeks of the current quarter the mean annual death-rate in these towns averaged 21·9, against corresponding rates of 18·4 and 20·1 per 1000 in the English and Scotch towns respectively. The death-rate last week was equal to 19·0 in Dublin (against 18·2 in London and 21·1 in Glasgow), 19·8 in Belfast, 17·7 in Cork, 24·0 in Londonderry, 19·0 in Limerick, and 17·1 in Waterford, while in the 21 smaller towns the mean death-rate was 17·8 per 1000.

The 444 deaths from all causes were 77 fewer than the number in the previous week, and included 35 which were referred to the principal epidemic diseases, against 30 and 41 in the two preceding weeks. Of these 35 deaths, 11 resulted from measles, 10 from infantile diarrhœal diseases, 9 from whooping-cough, 3 from diphtheria, and 2 from scarlet fever, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 1·5, against corresponding rates of 2·0 and 3·3 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 16, 5, and 13 in the three preceding weeks, fell to 11 last week, and included 7 in Belfast and 2 in Dublin. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 3, 5, and 5 in the three preceding weeks, further rose to 10 last week, of which 4 were registered in Dublin and 2 each in Belfast and Lisburn. The fatal cases of whooping-cough, which had been 15, 11, and 20 in the three preceding weeks, fell to 9 last week, and included 5 in Belfast and 2 in Dublin. Of the 3 deaths attributed to diphtheria, 2 occurred in Dublin and 1 in Newtownards. The 2 fatal cases of scarlet fever were recorded in Belfast and Waterford.

The deaths referred to diseases of the respiratory system, which had been 158, 119, and 104 in the three preceding weeks, further declined to 84 in the week under notice. Of the 444 deaths from all causes, 131, or 30 per cent., occurred in public institutions, and 8 resulted from various forms of violence. The causes of 10, or 2·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the large English towns the proportion of uncertified causes did not exceed 0·6 per cent.

Glasgow Lock Hospital.—The 109th annual report of this institution (for the year 1914) shows that 300 patients were admitted to the hospital, as against 240 in 1913 and 251 in 1912. The number of patients who left irregularly, or before their cure had been completed, was 15. Of the total number of patients admitted during the year 205 were received for the first time, 69 for the second, 23 for the third, 2 for the fourth, and 1 for the eighth time. The 384 out-patients made 1070 visits, as compared with 217 out-patients with 501 visits in 1913. The out-patients of 1914 had all at one time been in-patients. The average period of sojourn in the hospital was 42 days, and the average age of the patients 24 years. The patients included infants and girls of most ages between 2 and 16. The financial statement shows the ordinary income to have been £1301 19*s.* 6*d.*, and the ordinary expenditure £1500 7*s.*, leaving a deficiency of £198 7*s.* 6*d.*, which compares with a deficit of £4 10*s.* 3*d.* in 1913. The extraordinary income consisted of legacies amounting to £131, and after deducting special expenditure there is a debit balance of £390 15*s.* 10*d.* to be carried to capital.

"Audi alteram partem."

THE MENTAL TREATMENT BILL.

To the Editor of The Lancet.

Sir,—The letter of Dr. Edwin Ash in The Lancet of May 1st emphasises the long-felt public want which the Voluntary Mental Treatment Bill introduced into the House of Lords last spring by the Earl Russell completely meets.

Both this Bill and that of Mr. Cecil Harmsworth aim at precisely the same object, for both enable early mental symptoms "in whatever case and from whatever cause" to be "treated" for a limited period without the usual legal certificate. The only difference is that Mr. Harmsworth's Bill provides no safeguards against abuse, and in the opinion of a great number who realise the danger it is felt there should be some guarantee that this power should be used solely in the interests of the sufferer.

In this Bill there is a complete disregard of such an assurance, and this omission may amount to the legal sanction of licence in the name of liberty.

I am, Sir, yours faithfully,
Robert Armstrong-Jones, M.D. Lond.

Claybury, May 4th, 1915.

To the Editor of The Lancet.

Sir,—Will you permit me to make reference in your influential columns to a few points in relation to the Bill "to facilitate the early treatment of mental disorder of recent origin arising from wounds, shock, or any other cause"; which definition makes it applicable to any case of slight mental loss of balance of whatever nature, among civilians as well as among soldiers.

The first announcement of the Bill described it as a "War Emergency" measure, and gave it to be understood that it was introduced for the benefit of the soldiers; but, as admirably pointed out in your leading article of last week, it has no application to soldiers as soldiers at all. The soldier, while he remains in the army, is not certified, the strict military control in which he is there held being quite sufficient as a form of detention. The plea of emergency on the soldier's behalf therefore falls to the ground. It is when the soldier, after discharge from the army, returns to civilian life that he runs the great risk, as a civilian, if still unrecovered, of being placed under detention (should this Bill pass) without the safeguard of any legal procedure or appeal to a magistrate. This is a very serious matter, since it applies to the whole civil population, and introduces a most dangerous innovation, under the specious plea of temporary urgent necessity. The real necessity at all times is that the individual alleged to be of unsound mind should have his case fairly and impartially sifted and be heard in self-defence. Before the passing of the Lunacy Act, 1890, the public had been sharply roused to a realisation of the subterranean perils to which any of them might be at any time insidiously exposed.

A Bill is now brought in of retrograde tendency allowing a person of slight mental instability to be "taken charge of" for profit, and without penalty, for a period of six months, provided only that the person taking him in charge complies with certain regulations to be subsequently made by the Home Secretary and Lord Chancellor who represent the Executive of the Lunacy Commission. The Lunacy Commission is thus to be given the prerogative of substituting its permission or prohibition in this matter for the stringent provisions of the Lunacy Act, 1890. It is to make its own rules as to the conditions under which free British subjects may be "taken charge of" by "nursing homes" or other institutions run for profit, the legal safeguards of the Lunacy Act being meanwhile in abeyance. The House of Commons is asked, by endorsement of this extraordinary principle of the Bill, to "shut its eyes and swallow."

The Memorandum prefixed to the Bill gives us to understand the passing of the Bill is urgent on behalf of all kinds of patients suffering from nervous breakdown. It states that the law, as it now stands, prevents residential treatment of such cases unless they are certified as insane and sent to an institution under the Lunacy Acts. But there is no provision in English law which prohibits such cases being treated on medical lines in hospitals or homes so long as the patients are not "certifiable," and so long as compulsory detention is not exercised.

It would be well if the promoters of this Bill would give it clearly to be understood whether detention is included in Section 1 or not, the term "to take charge of" being extremely vague. If detention is not intended why bring in the Bill, since the law, as it stands, allows of treatment in hospitals or homes, provided the patient is not detained. The leading article in the *British Medical Journal* of May 1st is more explicit. It speaks quite unreservedly of curative detention and of the folly of insisting on the patient's freedom, where detention is necessary for cure. That is exactly the point. If detention has become necessary, the patient has become certifiable—i.e., it has become dangerous to leave him free—consequently his liberty must be restricted, and at the same moment, in consequence of the risk of unscrupulous dealings towards one unable to help himself, it is acknowledged on all hands, and has been strictly embodied in the Lunacy Act, 1890, that legal procedure is in this case obligatory, and appeal to judicial intervention necessary.

In the Memorandum prefixed to Mr. Harmsworth's Bill much stress is laid on the "stigma" which attaches to an individual who has been certified. It has even been asserted that if there were no legal procedure, there would be no stigma. This is a fatal confusion of ideas. It is not the provision for strict legal procedure that causes the stigma. It is the fact of the existence of a dangerous condition of mind necessitating detention. This necessity for detention originates the stigma, and not the law. The function of the law is protective, and we run into great danger if we allow detention to be exercised in contravention of the safeguards of the law.

The author of the article in the *British Medical Journal* speaks of a possible amendment to Mr. Harmsworth's Bill, to the effect that a patient may "accept" the treatment. But it does not need a Bill to oblige the patient to "accept." If the patient's mental state is such that he is uncertifiable, he can make the choice for himself without being obliged to do so by a Bill. It is a contradiction in terms to compel a so-called "voluntary" patient to accept treatment in an institution for the insane. The Bill brought in by Earl

Russell on July 22nd, 1914, had this aim. He himself explained at a Medico-Legal meeting on June 30th, 1914, that the patient would have no choice when sent in by a doctor; but the initial detention could not be continued against his will—i.e., in the event of his discovering that he had the right to leave. This would seem an anomalous arrangement. The writer in the *British Medical Journal* sums up his remarks by a suggestion which, he says, commends itself for its simplicity—viz., to adopt the last clause of Section 13 of the Scotch Lunacy Act, 1866, by which any doctor can send anyone to an asylum for six months on his own sole authority.

This measure, much as it may possibly commend itself to many doctors, will scarcely meet with the same unqualified approval from the great majority of British subjects. The writer says that for years the organised body of English alienists and expert opinion on lunacy has been calling for the incorporation of this measure into English law. It remains to be seen whether the public will also call for it. It is maintained that with the march of progress the question of disorder of the mind begins to be "regulated by scientific considerations."[1] This new consideration is, however, still in its extreme infancy. What we require above everything else is that all mental affections should be genuinely taken into account as a branch of medicine. Insanity is not and cannot be checked by the present methods of treatment. It is both unnatural and unscientific to regard mental treatment as a speciality, secluded from the light which might be thrown on it by every other branch of medicine. Mental treatment has often been of the crudest description, and has failed signally in reducing the prevalence of this worst of mortal ills. The reason of this is that its beginnings have been overlooked. The dread of the prison-bars of detention has stood in the way of every early effort at success. The only method by which the painful sense of indignity and utter insecurity can be removed, is to treat the earliest stages differently. We want places where early cases will not be afraid to come of their own accord for treatment—hospitals where prevention and common-sense will come into action much earlier. We want not more detention, but far less. We want free air and sunshine to penetrate into obscure recesses, and all the skill of medical care, therapeutic resource, and the best all-round intelligence to be brought to bear upon the treatment of derangement of our highest faculties, and this at its very earliest stage. How this can best be facilitated I must leave, with your kind permission, to a future occasion.—I am, Sir, yours faithfully,

S. E. WHITE, M.B. Lond.

Upper Montagu-street, W., May 4th, 1915.

THE MANUFACTURE OF SALVARSAN PRODUCTS IN ENGLAND AND FRANCE.

To the Editor of THE LANCET.

SIR,—I have read in your issue of last week Dr. David Watson's criticisms on my letter of April 3rd, in which he suggests that my diagnosis of arsenical poisoning following an injection of novarsenobenzol "Billon" was incorrect, and that the symptoms might have been "partly or entirely" due to "a mercurial dermatitis." I can only say that it is unprecedented for a case of mercurial dermatitis to persist for nearly four months, and notwithstanding treatment to still show symptoms of that condition; the patient referred to is still in hospital, and the skin over his whole trunk and lower limbs is at the present moment of a brick-red colour and is covered with branny desquamation. If this is Dr. Watson's experience of mercurial dermatitis I am happy to say that that condition is not met with in this metropolis.

In his apologia for Burroughs and Wellcome's preparation kharsivan Dr. Watson states that he has produced sufficient evidence to warrant the conclusion that a dose of 0·6 grm. of that substance is inadvisable; but that firm, in one of their leaflets with which the medical profession is not altogether unfamiliar, states that "kharsivan is to be used in precisely the same manner and dosage as the German product." Dr. Watson further states "that salvarsan is not less toxic than kharsivan in similar dosage is proved by our records," and therefore I presume there is nothing more to be said, though I have given some thousands of injections of salvarsan without having met with any such untoward symptoms as those described in your issues of April 3rd and May 1st.

It is perhaps somewhat *mal à propos* that immediately preceding Dr. Watson's letter in THE LANCET last week there appears my communication of two further cases of arsenical poisoning following injections of kharsivan, one of which unhappily proved fatal. Possibly Dr. Watson will be able to explain this case to his own satisfaction, but the position is this: a healthy young man contracts syphilis; he is given two intravenous injections of kharsivan; he develops symptoms of arsenical poisoning from which he dies one month later, and as to the diagnosis of death there can, unfortunately, be no mistake.

I am, Sir, yours faithfully,

J. ERNEST LANE,
Surgeon to the London Lock Hospital.

Queen Anne-street, W., May 2nd, 1915.

CLINICAL RESULTS OF KHARSIVAN, BILLON, AND NEOKHARSIVAN.

To the Editor of THE LANCET.

SIR,—The following results of the injection of these drugs may be of interest at the present moment.

Kharsivan.

No. of cases.	Headache.	Vomiting.	Temperature.	Other ill-effects.
78 (25 with no previous arsenical treatment): Primary 2, secondary 50, late secondary 24, tertiary 2.	10%	5%	12·5%; maximum 100·8° F. No temperature in 7 cases with our own re-distilled water.	Nil, except 1 case of bronchial pain lasting 2 days.

Kharsivan is an arsenical preparation made by Messrs. Burroughs, Wellcome, and Co., having a formula exactly similar to salvarsan ("606")—$C_{12}H_{12}O_2N_2As_2(HCl)_2 2H_2O$. It is a yellow acid powder dissolving with some difficulty in water and rather darker than "606." To prepare the drug for intravenous injection 250 c.c. of 0·5 per cent. saline solution made with doubly distilled water and a 15 per cent. solution of caustic sodium hydroxide are required.

According to directions 30 c.c. of doubly distilled water were put in a narrow graduated stoppered flask, to this the powder was added, and the whole shaken vigorously until the powder dissolved (latterly saline was used and the powder dissolved in it equally well). Caustic sodium hydroxide solution 15 per cent. was then added, until the precipitate first found cleared. Sterile saline solution was next added up to 250 c.c.; the solution often became cloudy on adding the saline, and then caustic sodium hydroxide was added drop by drop until after vigorous shaking the solution remained clear. The quantity of 15 per cent. solution needed varied considerably, 14 minims being the least used, 34 minims the most, for a 0·4 gramme dose. In all cases the solution was tested with litmus paper, and never gave more than a faintly alkaline reaction. The solution was always given cold and intravenously, and in no case was a vein cut down upon.

---

[1] See article in Times.

In every case saline or distilled water was run in before and after the kharsivan. The addition of saline to run in after the injection caused the last part of the solution to become cloudy. Distilled water had not this effect to the same extent. In seven cases our own doubly distilled water was used with *no* after-effects at all. The dosage given never exceeded 0·45 gramme. In a large majority the dose was 0·4 gramme. All the patients were females.

Billon.

This drug was first prepared by one of us with unsatisfactory distilled water, in that the still was old and useless, and it was found that the water was seldom doubly distilled.

Billon with Unsatisfactory Water.

No. of cases.	Headache.	Vomiting.	Temperature.	Other ill-effects.
19 (secondary 15, late secondary 4).	36·8 %	15·7%	52%. Maximum 103° F.	Rigors 15·7%

In the three patients who suffered from rigors these occurred ½ hour, 1½ hours, and 5 hours after injection. In two of the cases too large a dose was given—viz., 0·6 gramme to children of 15 years.

Billon with Satisfactory Water.

No. of cases.	Headache.	Vomiting.	Temperature.	Other ill-effects.
31 (primary, 12, secondary 12, tertiary 7).	6·4%	3 %	Nil.	Nil.

Of the 26 cases given at the Lock Hospital (18 secondary and 8 late secondary), 10 had had no previous arsenical treatment.

Novarsenobenzol "Billon" is the dioxydiamido-arsénobenzol (monométhylène) sulfoxylate de soude—viz., "914." It is of French preparation, the manufacturers being Poulenc Frères. It consists of a yellow powder, darker and more yellow than the original "914," very soluble in water, forming a perfectly clear yellow solution. To prepare the powder for use it was dissolved in 20 to 30 c.c. of doubly distilled water and given intravenously, a small quantity of the water being introduced before and after the drug. The dosage given was from 0·45 gramme to 0·6 gramme, the patients being both male and female. One of us gave 24 injections of "Billon" to private cases, mostly male patients, who received 0·6 gramme, but one female patient with the same dose vomited and suffered from headache; she had no temperature. She was suffering from two alveolar abscesses at the time. The others had no after-symptoms whatever. All had had no previous arsenical treatment.

Neokharsivan.

No. of cases.	Headache.	Vomiting.	Temperature.	Other ill-effects.
36 (10 had bad no previous arsenical treatment): Primary 3, secondary 21, late secondary 12.	14%	2·6% (1 case).	2·6% (1 case—i.e., 1 case of 102·4°).	Rigor occurred in the 1 temperature case.

In the one case of rigor, pyrexia, and vomiting, the rise in temperature occurred about four hours after injection. The patient was perfectly well 24 hours later. There was no reaction with a previous and a later dose of kharsivan.

Neokharsivan is prepared by Burroughs, Wellcome, and Co., and is declared to be identical in essential particulars with "914." It is a yellow powder, a little darker than "914," very easily soluble in water, yielding a clear solution. For intravenous injection the powder was dissolved in from 30 to 60 c.c. of doubly distilled water, doubly distilled water being introduced before and after the drug. The dose given ranged from 0·45 to 0·6 gramme.

General remarks.—The intervals between the injections varied in different cases from one to five weeks, there being two routine treatments used: (*a*) at intervals of seven to ten days, (*b*) at intervals of one month, all patients receiving full doses of mercury.

The hospital patients had the following preparation:—Pil col. cum hyosc., 4 grs., at 6 P.M.; mist. alb. at 2 A.M.; en. sap. at 5 A.M.; glass of hot milk at 10 A.M., and nothing more for four hours before injection. These patients remained in bed until the afternoon of the following day and took no solid food for about 24 hours after injection. The preparations were always given cold and as soon after mixing as possible, the bottle being kept well stoppered and tightly corked until the drug was used. Ether was rubbed over the vein before the insertion of the needle.

An aperient was administered to private patients on the preceding day, no breakfast, but a cup of tea and a piece of toast at 8 A.M., the injection being given at 10 A.M.; this was followed immediately by an ordinary breakfast, after which the patient remained in bed from two to six hours only.

Results.—The results of these three drugs were entirely satisfactory when we were using doubly-distilled water of assured purity. All the patients (164) were improved in health and increased in weight. The disappearance of symptoms seemed to be much the same as in Ehrlich's last preparations. Some cases which had failed to respond to mercury responded readily to arsenic. This was very noticeable in three cases of iritis. Four of the patients were suckling and the babies suffered no ill-effects. No local disturbance was noticed in the vein of the arm. All were perfectly well 48 hours after the injections and to the present date. The Wassermann results in private cases were negative. The urine was free from albumin except in one case—slight for two days only.

Headache is the only symptom which is more marked in these drugs than in Ehrlich's preparations, notably in female patients; in the male patients it very seldom occurred. The severity of the preparation and the starvation after the injections may be the causes of this headache in the hospital (female) cases.

Vomiting and temperature are at a minimum with pure water; only one rigor occurred in all the injections with pure water. We are convinced that the high percentage of temperatures in kharsivan injections is due entirely to the use of unsatisfactorily distilled water.

Dosage.—The general dosage used was 0·4 gramme kharsivan and 0·45 to 0·6 gramme of billon and neokharsivan. It will be understood that this moderate dosage was employed because we were dealing with new and untried drugs.

In conclusion, it must be noted that these results, although satisfactory, would have been even better if all the water used had been of assured purity. Granted that the distilled water is satisfactory, with a good technique and appropriate dosage we are persuaded that the British and French chemists have overcome the main difficulties and have produced drugs of equal utility to those of our more "cultured" enemy.

We are, Sir, yours faithfully,
CHARLES GIBBS, F.R.C.S. Eng.,
Surgeon to London Lock Hospital
and to Charing Cross Hospital.
MORNA RAWLINS,
House Surgeon to London Lock
Hospital.
May 1st, 1915.

ENTERIC FEVER DUE TO A URINARY CARRIER OF LONG STANDING.

To the Editor of THE LANCET.

SIR,—The following small outbreak of enteric fever, due to a carrier, appears to me to be of sufficient interest to place on record. It occurred last autumn at the Alexandra Palace while that building was being used for the reception of Belgian refugees. Between the commencement of October and the end of November five members of the staff developed this disease. The first to fall ill was a clerk working in the trustees' office, the second was a waiter in the staff dining-room, the third waited on the better-class refugees, the fourth on the general body of refugees, while the fifth and last was the night nurse on duty in the hospital ward where there had been no case of enteric fever for six weeks. These five individuals, consequently, were all working in different parts of the building. They had only one thing in common, and that was the preparation of their food by the cook who was in charge of the staff kitchen. On being questioned this man stated that he had suffered from enteric fever 18 years ago, and was in St. Mary's Hospital for six months. I obtained specimens of his excreta, which were bacteriologically examined for me by Dr. G. E. Cartwright Wood, who reported that the bacillus typhosus was present in the urine but was not found in the fæces. In answer to my inquiries, the man informed me that he had never at any time suffered from pain or discomfort in the region of the bladder, nor from frequency of micturition; nor had he ever noticed anything unusual in the appearance of his urine. I was not able to make any inquiries of previous employers of this man because for the last 16 years he has had no fixed employment, but has moved about the country acting as temporary cook at race meetings, during manœuvres, and at hotels.

The points of interest in this case are: (1) The long duration of infection in a urinary carrier; (2) the complete absence of bladder symptoms. After the cook's departure no further case of enteric occurred among the staff. I might add that there were only six cases of this disease among the 32,000 refugees who passed through the Alexandra Palace.

I am, Sir, yours faithfully,
HERBERT E. CUFF,
Principal Medical Officer of the Metropolitan
Asylums Board.
April 30th, 1915.

THE SCOTOMA OF MIGRAINE.

To the Editor of THE LANCET.

SIR,—Mr. Charles Higgens's observations in THE LANCET of May 1st are of great importance. A simple experiment which proves conclusively that the photo-chemical stimulus is external to the cones may be made as follows. On arising in the morning arrange a mirror so that the sun is reflected from its surface, then whilst one eye is closed and covered with the hand the other eye is opened and closed so that the image of the sun is visible for a fraction of a second; both eyes being now closed and covered with the hands a clear-cut after-image of the sun is seen on a dark background. It will be noticed that there is nothing else visible in the field of vision. If the head be now moved rather sharply to one side the after-image will be drawn out into a long sausage-shaped form with irregular knobs on it. If the head be sharply jerked we can obtain several after-images, plainly showing that the photo-chemical stimulus is movable in the retina and therefore cannot be situated in the cones. I find these experiments succeed best in the morning immediately after sleep, probably because the processes of the pigment cells are retracted. If any reader find that he cannot see any of the subjective phenomena described by me I would suggest that he select one of the most accurate observers of his acquaintance and ask him to repeat the experiment without giving him the least clue as to what he is to see. If he describe the phenomenon as I have described it, it is obvious that we have obtained important confirmatory evidence. I find that whilst many older men fail to see various subjective phenomena they are rarely missed by the young.

I am, Sir, yours faithfully,
London, May 1st, 1915. F. W. EDRIDGE-GREEN.

THE BACTERIAL INFECTIONS OF PROJECTILE WOUNDS.

To the Editor of THE LANCET.

SIR,—In the leading article under the above title in your issue of April 24th, as well as in the illuminating address of Sir Almroth Wright and the "Memorandum on the Treatment of the Bacterial Infections of Projectile Wounds" in the same issue, stress is laid on the importance of free drainage of these wounds and of the necessity of securing "a free outflow of lymph"—and Sir Almroth Wright and the other writers mention the various means adopted to secure these ends. But I see that there is no mention of the use of "Bier's method" of evacuating abscesses and sinuses by means of cupping glasses and other forms of aspiration.

Are there not cases where this method would be useful—especially when two or three days have elapsed after the injury? By suction or aspiration pent-up matter is evacuated and "a free flow of lymph" and an "active hyperæmia" are induced.

I am, Sir, yours faithfully,
Llandrindod Wells, April 29th, 1915. R. ACKERLEY.

THE TREATMENT OF CALLOUS ULCERS.

To the Editor of THE LANCET.

SIR,—Mr. H. Beckwith Whitehouse, in his report on gunshot and shell wounds in THE LANCET of April 24th, speaks of the use of glucose in causing osmosis and promoting rapid healing. Strangely enough, for many years I have used cane sugar in medium-sized crystals to soften callous ulcers on account of the free passage of lymph over the surface of the ulcer when the crystals are dusted over it. This is a wrinkle that I picked up from an old woman who was curing an ulcer on her leg in this manner. How or where she got the idea I never learned, and I never saw anyone but herself use it.

Progressive gangrene with a tough yellow slough continually increasing in depth and thickness may possibly, as far as I know, be found in some wounded in this war. A case that came under my care in civil life caused me great worry and anxiety. All I could do was unavailing, until I allowed steam direct from a kettle-spout to play on the slough; this rendered it friable, and I was able to clear it away down to the raw, living flesh, the blood-vessels and nerves which were dead remaining as strings hanging from the surface. Rapid healing followed the use of antiseptic dressings.

I am, Sir, yours faithfully,

Bradford, Yorks, April 27th, 1915. P. M. O'BRIEN.

TREATMENT OF "INCRUSTED CYSTITIS" BY SUPRAPUBIC DRAIN AND INTRA-VESICAL INJECTION OF LACTIC BACILLUS.

To the Editor of THE LANCET.

SIR,—I agree with Dr. David Newman, in your issue of May 1st, that Dr. Caulk cannot claim priority in regard to the action of the lactic acid bacillus on other infections. I fancy the credit should belong to Metchnikoff, for surely he first demonstrated scientifically the effect of this bacillus on bacilli coli. I have myself for some years used *lactic acid* for infections of the bladder. I first used it in two cases with dense phosphatic incrustations and was delighted with the result. Subsequently I had experiments made as to the bactericidal potency of solutions of different strengths in respect to bacilli coli, and we found that a solution of 1–10 was the minimum strength that was likely to be effectual. I also had tested the solvent power of this acid on vesical calculi. It was found that in the strength of 1–10 it is a weak solvent, but is able to dissolve small phosphatic spicules within a reasonable time and to soften and so assist the disintegration of larger masses. Unfortunately, illness and other circumstances prevented the publication of these observations, but I hope to record them some day.

Meanwhile I would advise the use of a 10 per cent. solution of lactic acid rather than the lactic acid bacillus for two reasons: (1) lactic acid must be in a fairly strong solution if it is to act as a solvent as well as a preventive of phosphatic deposits; (2) the stronger the solution the greater the bactericidal potency. It will be found that lactic acid in the strength recommended causes considerable pain when injected into the bladder, but if a weak solution of novocaine be first injected into the bladder and allowed to remain there for a few minutes the pain is prevented. The solution of lactic acid should be injected into the empty bladder and left there for 15 minutes. It should then be washed out with saline. These procedures should be repeated as often as is considered necessary. In bad cases suprapubic (*not* vaginal) drainage should be employed.

I may add that I have used lactic acid in the same strength for intractable leucorrhœa due to bacillus coli infection. Some years ago I showed that the lactic acid normally found in the vagina is not necessarily produced by the action of Döderlein's bacillus since this acid is present in sterile hæmatocolpos fluid.[1]

I am, Sir, yours faithfully,

Liverpool, May 3rd, 1915. W. BLAIR BELL.

CERTAIN PECULIAR CRYSTALS FOUND IN CEREBRO-SPINAL FLUID.

To the Editor of THE LANCET.

SIR,—I have read with interest the article of Dr. W. W. D. Thomson in THE LANCET of March 27th on the occurrence of peculiar crystals in the cerebro-spinal fluid for the reason that shortly before the outbreak of war I encountered a similar case myself. From the clinical side the case was very obscure. The only outstanding feature was very marked secondary optic atrophy, together with a slight degree of headache. There were no other symptoms of cerebral tumour, and, apart from a slight degree of anæmia, the patient appeared to be in perfect health. The Wassermann reaction was negative. The cerebro-spinal fluid was perfectly clear, under slightly increased pressure, showed no cellular or protein increase, but contained enormous numbers of crystals, which appeared to be identical in appearance with those described and figured by Dr. Thomson. They refused to take up any stain. It was impossible to determine the nature of these crystals until they were put under the polarising microscope, when they were at once seen to be the highly, doubly refracting crystals of a cholesterin ester. No crystals of cholesterin could be seen. The crystals were present in the cerebro-spinal fluid on four separate occasions. If Dr. Thomson should be fortunate enough to come across another case of this description he might find it of interest to examine the fluid with the polarising microscope and compare the crystals with a known specimen of a cholesterin ester.

Mr. Ernest H. Shaw's suggestion that the crystals were deposited from the water used for sterilising the tube appears to me a most extraordinary one, and I am glad to see that Dr. Thomson has completely refuted it.

I am, Sir, yours faithfully,

WILLIAM BOYD,
Lieutenant R.A.M.C.(T.); Professor of Pathology,
University of Winnipeg.

1/3rd North Midland Field Ambulance, British Expeditionary
Force, May 1st, 1915.

THE WAR OFFICE NEED FOR DOCTORS.

To the Editor of THE LANCET.

SIR,—Many of us middle-aged men would be willing to join the Royal Army Medical Corps, but at our age we have a strong objection to being under the orders of a captain aged 28 or so. I know it is impossible for the War Office to explain to each individually as to the nature of the duties expected of us, but it would be very helpful to some of us who are wavering if the authorities were to publish a general description of the kind of man they want, what his duties would be, and what would be the nature of the discipline which he would have to submit to.

I am, Sir, yours faithfully,
"52."

May 1st, 1915.

Obituary.

ALEXANDER MAXWELL ADAMS, F.R.C.S. EDIN., L.R.C.P. EDIN., L.F.P.S. GLASG.,

SURGEON-COLONEL (RETIRED), 3RD AND 4TH BATTALIONS SCOTTISH RIFLES; MEDICAL OFFICER OF HEALTH OF LANARK.

THE death of Surgeon-Colonel Alexander Maxwell Adams took place, after a somewhat long illness, at Friarsfield, Lanark, on April 9th.

Alexander Maxwell Adams, who was the son of Alexander Maxwell Adams, M.D., professor of medicine at Anderson's University, Glasgow, was born at Berwick on March 30th, 1837, and qualified L.F.P.S. Glasg. in 1857. He became L.R.C.P. Edin. in 1860, F.R.C.S. Edin. in 1875, and D.P.H. in 1890. He was Surgeon-Lieutenant-Colonel of the 3rd and 4th Battalions Scottish Rifles and served in the South African campaign. He was medical officer to the Lady Hozier Convalescent Home and the Smyllum Orphanage, surgeon to the Lanark Poorhouse and to the Lockhart Hospital, and medical officer of health of Lanark.

His all-round professional capacity made him an outstanding practitioner in the district in which he lived; he enjoyed for many years one of the largest practices in the neighbourhood, and his kindly manner gained him immediate acceptance among those who called upon him for aid. He was the first medical officer of health of the borough of Lanark, and held the position for 30 years. His term of office was marked by great sanitary reform, and he lived to see a decided improvement in the health of the district occasioned by his exertions. He was a member of the Lanark school board from 1885 to 1903, and served the office of chairman for two periods, from 1889 to 1891 and again from 1894 to 1903.

Dr. Adams leaves a wife and large family to mourn their loss, one son, Dr. D. A. V. Maxwell Adams, at present in the Royal Army Medical Corps, being with the British Expeditionary Force in France.

FREDERICK LAWRANCE, M.R.C.S., L.S.A.

Mr. Frederick Lawrance, who died in his eighty-fifth year on May 1st, was perhaps the oldest practising medical man. The son of the Rev. Robert Lawrance, rector for 21 years at Bleadon, near Weston-super-Mare, he was born at Kington St. Michael, near Chippenham. He received his medical education at St. Bartholomew's Hospital, qualified as M.R.C.S. in 1857 and L.S.A. in 1859, and became a partner of Dr. Loadman, of Hammersmith, going to reside in a house in Chiswick-lane, in which the poet Pope and his parents had at one time lived.

Mr. Lawrance was widely known, and at one time his practice was among all classes. He always enjoyed good health until about a year and a half ago, but he continued to practise almost until the day of his death, attending his last case of midwifery this year. His energy was such that he continued in active practice until he went into a nursing home two months ago for an operation, from which he made a good recovery. Indeed, he insisted upon giving directions about his patients to within three or four days of his death, notwithstanding the impairment of his speech due to the partial hemiplegia of which he had two strokes during the last month.

His activities were numerous and varied. He was chairman of the Conservative Association of Hammersmith, member of the board of management of the West London Hospital, a churchwarden, and was associated with very many local charitable and other institutions. He was also an ex-president, an original member, and one of the most regular attendants of the West London Medico-Chirurgical Society. Mr. Lawrance was initiated into Freemasonry in the Lodge of Harmony, and was a founder member of several Lodges and Chapters. He was a director of ceremonies at the Grand Lodge of England for the year during which King Edward VII., when Prince of Wales, was installed Grand Master. He was fond of all kinds of sport, and of riding and driving, was a good judge of a horse and in his younger days enjoyed fishing, shooting, and hunting. One of the most unselfish of men, he endeared himself to several generations of families that he had attended.

Mr. Lawrance married Miss Matilda Clark, youngest daughter of the late Dr. Clark, of Twickenham, by whom he had one child, a daughter. Both predeceased him by some years.

THE LATE DR. PANTLAND HICK.

A further appreciation has reached us of Dr. Pantland Hick, whose untimely death has left so deep an impression on his friends:—

"Life is short, and the Art long ......" Men must strive to achieve even though they live not to see the fruits of their endeavours and achievements. Thus did Hippocrates in his wisdom inscribe the epitaph of the many physicians, cut off in the vigour of youth, who were to follow him with devotion and faith through the long ages. Pantland Hick was such a man. He was absorbed in his work; he spared neither his energies nor his health. Indeed, he died serving his country with that same unselfishness that he lavished on his friends and patients in their hours of need. In these times memory is short and hopes are high. Men whose death would cause a stir in ordinary times pass almost unnoticed. But to those who knew him Hick will always be a living memory—the memory of a physician whose powers of observation and whose frank and noble disposition would have placed him among the great physicians of the country had he been spared to accomplish in his own modest but unswerving way that to which he had set his hand.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—The next quarterly (or general) meeting of this association will take place on Tuesday, May 18th, at 11, Chandos-street, Cavendish-square, London, W., under the presidency of Dr. David G. Thomson, at 3 P.M. On the same day and at the same place will meet: Nominations committee, at 10 A.M.; educational committee, at 11 A.M.; Parliamentary committee, at 12 noon; council, at 1.30 P.M.; and research committee, at 5.15 P.M. Papers will be read by Dr. T. B. Hyslop on Anger, and by Dr. David Orr on Research.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE EXECUTIVE COMMITTEE.

A MEETING of the Executive Committee was held on Thursday, April 29th, when good progress was reported. A letter was read from Dr. Pechère, the President of the Aide et Protection aux Médecins et Pharmaciens Belges, to Sir Rickman Godlee, in which the warmest thanks of that body were returned to the Fund for the donation in money which had been forwarded upon the decision of the committee at the previous meeting. To this letter a reply was sent by Sir Rickman Godlee stating the intention of the Fund to continue to help in this way, and asking that details of the distribution should be made known to the committee of the Fund. Sir Rickman Godlee also read a letter from Mr. Herbert Hoover, saying that for the moment it would not be possible to communicate with Belgium or to receive from Belgium the information sought.

A letter was also read from the Under Secretary of State for Foreign Affairs explaining the circumstances in which His Majesty's Government decided that they would not be able to make a monthly contribution out of public funds to the benevolent department of the American Commission for Relief in Belgium. It was decided that a copy of this letter should be sent to the chairman of one of the American Funds having similar objects to those of the British Fund, because the position of the British Government in the matter might be misinterpreted in the United States.

Dr. Des Vœux and Dr. Squire Sprigge said that their experiences were alike at the present moment with regard to finding situations for Belgian doctors in this country. At one time there appeared to be little difficulty in finding the posts, while the applicants were not coming forward. Now there seemed to be many vacant appointments, but for one reason or another the Belgian candidates were not successful in obtaining them.

The treasurer's report showed that money was coming in steadily, though many districts had not yet responded to the invitation to subscribe. Dr. Alfred Cox said that in the forthcoming annual report of the British Medical Association the claims of the Fund would be repeated. It was generally felt by the committee that though the outgoings at the time were not large, the call upon the Fund in the future would be very heavy, and that no pains ought to be spared to augment its resources.

Messrs. Burch, Whitehead, and Davidsons, 29, Spring-gardens, London, S.W., have kindly consented to act as honorary solicitors to the Fund.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions received by Dr. Des Vœux during the week ending Tuesday last make a total of very nearly £2000, but this handsome sum, of course, includes a donation, on account, from the Scottish Committee, Belgian Doctors' and Pharmacists' Relief Fund, of £1000. From the Liverpool Belgian Doctors' Relief Fund there was received £400, the sum being earmarked for the relief of doctors, as a separate fund has been instituted in Liverpool for pharmacists. A further welcome donation of £400 was received through the Australian Agent-General from the Australasian Pharmaceutical Conference.

Mr. R. Fouracre	0	5	0
Dr. A. W. Sanders... ...	1	0	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments kindly contributed by the following donors:—

Dr. Flora Butcher, Tanakpur, U.P., India; Dr. J. C. Eames, Stoneclough, Manchester; Dr. W. H. Hargreaves, Dr. R. G. S. Orbell, Dr. J. Whitton, and Dr. Scott (per Mr. W. H. Rose, chairman, Oamaru Hospital, New Zealand).

DONATIONS AND BEQUESTS.—By the will of the late Dr. Arthur Wigelsworth Orwin the Central London Throat Hospital will receive £1000.—The late Alderman John Royle, of Manchester, bequeathed £1000 each to the Ancoats Hospital, Manchester, Henshaw's Blind Asylum, Old Trafford, and the Manchester Royal Infirmary. Subject to certain gifts of shares, the testator left the residue of his property as to three-fifths to the "David Lewis Epileptic Colony," Sandle Bridge, Cheshire, and as to two-fifths as his trustees may see fit among charities mentioned in his will.—King Edward's Hospital Fund will receive £60,000 under the will of the late Mr. Edward Berman, in the event of certain legacies and a life-interest failing.—A sum of £250, part of the fund placed at the disposal of the Queen by the wives of Freemasons, has been given by Her Majesty to pay for the training and expenses of a medical student at the London School of Medicine for Women.—Sir Joseph Jonas, chairman of the Applied Science Committee of the University of Sheffield, has given £5000 to found, endow, and equip a testing laboratory in connexion with the Applied Science Department of the University.

The War.

THE CASUALTY LIST.

THE casualty lists published since our last issue contain the following names of medical officers:—

Killed: Fleet-Surgeon Adrian A. Forrester, R.N.

Wounded: Captain J. L. Duval, Captain R. H. McGibbon (both of 1st Field Ambulance, Canadian Forces), Captain C. A. Wood (attached to 1st Battalion, 4th Gurkha Rifles), I.M.S.; Lieutenant H. S. de Boer, Lieutenant G. L. K. Findlay, Lieutenant J. A. MacMahon (attached to 1st Battalion, Somerset Light Infantry), all of the R.A.M.C.; Major W. M. Mackay, Major F. G. Proudfoot, Captain J. M. Bowie, Captain D. H. Weir, Lieutenant R. E. Barnsley, Lieutenant V. H. Wardle, all of the R.A.M.C. (T.F.).

Missing: Lieutenant C. Stenhouse, R.A.M.C. (T.F.).

THE HONOURS LIST.

The Indian Distinguished Service Medal, in recognition of their gallantry and devotion to duty whilst serving with the Indian Army Corps, British Expeditionary Force, has been conferred on the following native medical officers: First-class Senior Sub-Assistant Surgeon Gaurie Shankar (112th Indian Field Ambulance) and Third-class Sub-Assistant Surgeon Zafar Husain (129th Indian Field Ambulance).

WHAT ANTITYPHOID INOCULATION HAS DONE FOR THE ARMY.

In our parliamentary columns will be found a statement by Mr. Tennant of the number of cases of typhoid fever that have occurred in the Expeditionary Force from the outbreak of the war to the beginning of May, which shows that the case-mortality among those protected was between 6 and 7 per cent., while among those unprotected it amounted to over 20 per cent. We cannot, of course, in the absence of a statement as to what proportion of the entire army was fully protected, what partly protected, and what entirely unprotected, draw indisputable conclusions as to the immunity conferred in regard to case incidence, but seeing that the environment and other modifying conditions, so far as these several classes were concerned, must have been practically identical, it is obvious that the effect on the mortality of the disease was very great indeed. Sir Berkeley Moynihan, speaking recently to a professional audience at Leeds from his own observations at the front, expressed the conviction, based on his own experience, that antityphoid inoculation had clearly reduced the incidence of typhoid fever, mitigated its severity, and, above all, considerably diminished its mortality.

THE GERMAN USE OF ASPHYXIATING GASES.

Under date of May 4th Sir John French has issued the following report on the use of asphyxiating gases in warfare and on deadly and cruel effects upon those exposed to them:—

> The gases employed have been ejected from pipes laid into the trenches, and also produced by the explosion of shells especially manufactured for the purpose. The German troops who attacked under cover of these gases were provided with specially designed respirators, which were issued in sealed pattern covers. This all points to long and methodical preparation on a large scale.
>
> A week before the Germans first used this method they announced in their official communiqué that we were making use of asphyxiating gases. At the time there appeared to be no reason for this astounding falsehood, but now, of course, it is obvious that it was part of the scheme. It is a further proof of the deliberate nature of the introduction by the Germans of a new and illegal weapon, and shows that they recognised its illegality and were anxious to forestall neutral, and possibly domestic, criticism.
>
> Since the enemy first made use of this method of covering his advance with a cloud of poisoned air he has repeated it both in offence and defence whenever the wind has been favourable.
>
> The effect of this poison is not merely disabling or even painlessly fatal, as suggested in the German press. Those of its victims who do not succumb on the field and can be brought into hospital suffer acutely, and in a large proportion of cases die a painful and lingering death. Those who survive are in little better case, as the injury to their lungs appears to be of a permanent character and reduces them to a condition which points to their being invalids for life. These effects must be well known to the German scientists who devised this new weapon and to the military authorities who have sanctioned its use.
>
> I am of the opinion that the enemy has definitely decided to use these gases as a normal procedure and that protests will be useless.

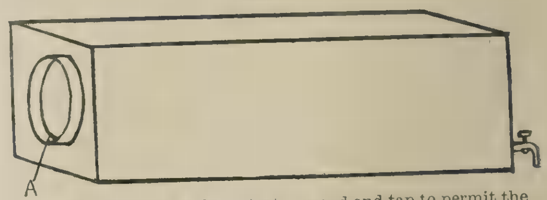
CONTINUOUS BATHS FOR SEPTIC WOUNDS OF THE LEG.

Mr. Malcolm Donaldson, F.R.C.S. Eng., Temporary Lieutenant, R.A.M.C., has sent us the following description of the apparatus which he has designed for the treatment by continuous baths of septic wounds of the leg:—

"In looking through the medical journals for the last few months it at once becomes obvious what a variety of opinion there is concerning the treatment of the intensely septic wounds of the leg which are a feature of the present war. Such controversies tend to show that up to the present no royal road to cure has been found.

The base hospital to which I am attached is the furthest from the front; consequently some of the casualties arrive with wounds in a state of sepsis; therefore it may be of interest to mention the treatment which, in my limited experience, has proved most beneficial, and to describe a leg-bath which can be used with the patient in the horizontal position, without the water finding 'its own level' in the mattress and bedding.

FIG. 1.

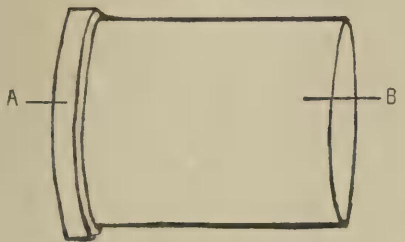


The box bath with collar (A) at one end and tap to permit the flow of water at the other.

It is obviously useless to put a limb in a bath if there is not free drainage. A few hours after the patient is admitted, and when he has recovered from the fatigue of the journey, he is taken to the theatre and the limb thoroughly opened up. Like most people, since the beginning of the war I have been forced to realise more and more that large incisions and multiple counter drains are absolutely essential. A few hours later, when all hæmorrhage has ceased, the limb is put into the bath (described below). At first various antiseptics were tried, but lately, hypertonic solution of salt (from 4 per cent. to 10 per cent.) has been used.

The results of this treatment, especially since the salt solution has been used, are most striking. The limb is left in the bath from 24 to 48 hours, the solution being changed at intervals, and kept at a comfortable temperature. It is then fomented for 12 hours before it is again put in the bath. The relief to the patient is very great, and they often beg to have their legs left in the bath. It is better to increase the strength of the salt slowly, and then the patient does not feel the stinging sensation for more than a few minutes. At the end of 24 hours the leg is often very swollen as the result of the saline, as can be proved by comparing it with other solutions. The patients drink large quantities of fluid during this treatment, and it is found that the discharge from the wound is greatly increased for several hours after removal of the limb from the bath, the sloughs coming away easily.

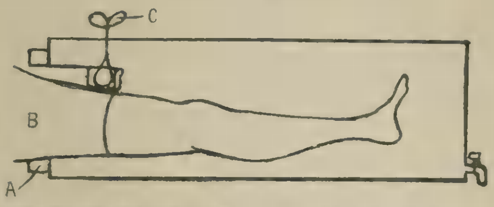
FIG. 2.



The collar A, and rubber sleeve B, through which the limb is passed. The rubber sleeves can be obtained from Messrs. Cow, Cheapside, London.

This bath (Fig. 1) is made of zinc or galvanised iron with the following dimensions: Length, 3 ft.; width, 10 in.; depth, 1 ft.; it has a circular hole at one end 30 in. in circumference. On the outer side is a metal collar or a flange which projects 1½ in. On to this collar a rubber sleeve (Fig. 2) is fitted, the other end of the sleeve being clamped on to the thigh after the leg has been introduced into the bath. (Fig. 3.) There is no need for the rubber to be very much stretched, as the pressure of the water helps to keep it watertight. The dimensions of the rubber sleeve are: length, 12 in.; circumference, 26 in.; with a thick band over one end to fit over the collar.

FIG. 3.



The limb immersed in the bath. The rubber sleeve B, which is attached to the collar A, is drawn taut on the limb by the clamp C, preventing trickling of water from the bath.

I am much indebted to my engineering friend, Mr. H. Wingfield, for helping me to design the bath."

VACANCIES FOR MEDICAL OFFICERS.—We are asked to state that there are still a few vacancies for medical men wishing to take commissions in the 1st London (City of London) Sanitary Company. As the duties of this company consist in organising and supervising the sanitary work of the army at the front and at home, it is desirable that applicants for commissions in this company should have a knowledge of sanitation. The posts are especially suitable for men in the Public Health or Education Service who can be released by their councils for military work. Those joining at once may expect to be ordered abroad at an early date. Applications for commissions should be made to the Officer Commanding, 1st London (City of London) Sanitary Company, Room B 6, Duke of York's Headquarters, Chelsea, S.W.

MEDICAL RELIEF FOR SERBIA.—The second hospital which was being despatched to Serbia by the British Farmers' Red Cross Fund to combat the spread of typhus fever, as well as the Serbian unit of the Scottish Women's Hospitals, has been temporarily detained at Malta on the requisition of the Governor, its services there being urgently required.

The Wounded Allies Relief Committee have appointed Dr. R. Fleming Jones as head of their Serbian typhus hospital at Kragujevac, where during the month of March there were over a thousand cases of recurrent or enteric typhus. Dr. Jones has had exceptional experience in this kind of work, not only in the Spanish-American War, but also in New Guinea where for the past three years he has been chief medical officer. The Wounded Allies Relief Committee's No. 2 Home for Disabled Belgian Soldiers, 45, Courtfield-gardens, Kensington, which accommodates about 50 men, will be formally opened at 4 P.M. on Monday, May 10th, by Her Imperial Highness Princess Napoleon (Princess Clementine of Belgium).

THE CARE OF THE WOUNDED IN IRELAND.—The hospital ship *Oxfordshire* arrived in Dublin from France on Friday, April 30th, with 13 officers and 826 men wounded in the fighting round Ypres. Of these rather less than half were distributed among the Dublin hospitals, the remainder being sent some to Belfast, some to Cork, and some to various other centres. The patients were for the most part not so gravely wounded as the last party that arrived in Dublin. Those despatched to Belfast travelled by the Great Northern Railway Company's hospital train and were distributed as follows: 22 were sent to the Royal Victoria Hospital (of whom 20 were severe stretcher-cases), 24 were sent to the Mater Infirmorum Hospital, 22 to the Samaritan Hospital, and 53 to the Ulster Volunteer Force Hospital. Of the remainder, 25 were sent to the Waveney Hospital, Ballymena, and 6 to Dumbarton House, Gilford, where a hospital has been established, under the auspices of the Ulster Volunteer Force. Complete arrangements have been made for the reception, comfort, transport, and treatment of the wounded soldiers. On May 1st another draft of 126 sick and wounded soldiers were sent from Dublin (where they disembarked) to the north of Ireland, and were divided among the above hospitals, as well as the county infirmaries at Omagh and Londonderry and at Downpatrick.

ST. MARYLEBONE WAR HOSPITAL SUPPLY DEPÔT.—This depôt, to the establishment of which through the generosity of Mr. James Boyton, M.P., brief reference was made in our issue of May 1st, is now open to inspection at 32, Queen Anne-street, Cavendish-square, W., between 10 A.M. and 6 P.M. It contains rooms allotted severally to the following purposes: Bandages, surgical dressings, splints, pine dressings, needlework, slippers, linen, stock and sorting, and carpenter's work. All the articles are sent out in response to a direct appeal from some hospital abroad that is urgently in need. The weekly subscription of 1*s.* each contributed by all the voluntary workers covers the running expenses, so that the whole of any donation received passes direct to the purchase of material required for making supplies. Donations of money, also of blankets, socks, rubber hot-water bottles, and old linen, will be gratefully received by the hon. sec., Mr. F. A. Juler, at the above address.

WAR EMERGENCY COURSES FOR CIVIL PRACTITIONERS.—A Glasgow correspondent, who signs himself "Emergency," writes as follows: "In THE LANCET of March 27th and April 3rd there are paragraphs to the effect that the Russian and Italian Governments have requested the medical authorities to give to senior students and practitioners short courses in practical emergency surgery and field hygiene. Is anything being done in this country in this direction? Many civil practitioners will feel uncertain of themselves when faced with work they are unaccustomed to. A short course in the essentials of these subjects would dispel this uncertainty and immensely increase the efficiency and usefulness of these practitioners."

"Flag Day" in Belfast.—The Belfast Rotary Club is to be congratulated on the phenomenal success of an undertaking originated by them, the object of which was to aid Belfast's wounded sailors and soldiers. All over the city on April 30th ladies were active in selling flags of the Allies in the present war—English, French, Russian, Japanese, Belgian, and Serbian. The nominal price of each flag was 1*d.*, but as much as £5 were cheerfully paid. As a result the sum of £2667 2*s.* will be available, and it is to be distributed through "The Soldiers' and Sailors' Help Society." Over £90,000 have already been subscribed in Belfast to special funds in connexion with the war, a sum far beyond that contributed in any other city (or two cities) in Ireland.

A Handbook for War Time.—A useful reference book, with the title "All Can Help" and the subtitle of "A Handbook for War Time," has been issued by the Duty and Discipline Movement of 117, Victoria-street, London, S.W., at the price of 6*d.* It was first published in November, 1914, and revised and reprinted in March of this year. Its 95 pages contain a quantity of useful information such as How to Join the Forces, Pay, Separation Allowance, Territorial Forces, Reserve and Volunteer or Voluntary Corps, and a long list of naval, military, and social help agencies and societies, divided into sections of (1) For Sailors and Soldiers of the Allied Nations; (2) Funds for Relief of Civilians suffering through War; (3) Funds and Agencies for Helping Distressed Foreigners. In this last section is included the Belgian Doctors' and Pharmacists' Relief Fund (where, it may be pointed out, the chairman is incorrectly described). There are also special chapters treating generally of the Family in War Time and the War and the Sentimentalists. Another edition would, in our opinion, be improved by a short alphabetical index of the whole contents, although some sections are more or less alphabetical in themselves.

Newcastle Surgical Aid Society.—The annual meeting of the Arnison Surgical Aid Society was held at the Royal Infirmary, Newcastle, on April 29th, when the report showed that during the year 1914 assistance had been given to 171 applicants. The amount paid for appliances was £260, towards which the patients had contributed £125. The working men of Newcastle had collected £70. Although the number of appliances supplied to poor people had not been so great in recent as in past years, owing to the work of the Insurance Committee and a School Teachers Fund for supplying spectacles to school children, it was pointed out in the course of the proceedings that during and after the war a large number of soldiers and sailors would apply to the society for aid. For this reason an earnest appeal was made for increased subscriptions.

"Tucked Sheets" for Hospital Use.—If a sheet is turned it is obvious that it will transfer to the bedding what it should carry to the wash to be removed. Mr. D. H. Shuttleworth-Brown, of Wimbledon, has devised a "tucked sheet," the tuck serving to obviate the possibility of a sheet becoming accidentally turned, and we are informed that its adoption at the King George Hospital and by the Red Cross Society is being supported by high surgical authority.

Flies in Warfare.—Professor R. Newstead, of the Liverpool School of Tropical Medicine, has been commissioned by the War Office to prosecute entomological investigations in France from the standpoint of military sanitation. He accordingly left for France on April 27th.

An Athletic Ground for the Royal Naval Division.—Football and sports grounds at the Crystal Palace have been allocated by the naval authorities for the use of the Royal Naval Division, and the equipment will be undertaken by the Young Men's Christian Association.

The Beaufort War Hospital.—The Bristol Lunatic Asylum at Fishponds is to be used for the reception of wounded soldiers. It will provide 1040 beds, and is to be called the Beaufort War Hospital.

A Munificent Benefactor.—It was reported at the annual meeting of the Nottingham Hospital on April 28th that the contributions of the late Sir Charles Seely to that institution had exceeded £100,000 in the last 20 years.

Medical News.

Examining Board in England by the Royal Colleges of Physicians of London and Surgeons of England.—At the Final Examination of the Conjoint Examining Board, held from April 6th to 22nd, the following candidates were approved in the under-mentioned subjects:—

Medicine.—A. C. Ainsley, Cambridge and London; D. W. J. Andrews, Middlesex; T. Anwyl-Davies, St. Thomas's; C. Backus, St. Mary's; C. W. W. Baxter, Guy's; M. Bayumi, Cairo and London; W. K. Bigger, Cambridge and St. Thomas's; S. C. Biswas, Calcutta and St. Mary's; C. V. Boland, St. Bartholomew's; J. P. Bracken, University College; H. F. Brice-Smith, Cambridge and Middlesex; A. D. Brooks, Royal Free; C. M. Brophy, University College; J. K. J. Chambry, Amsterdam and St. Mary's; F. B. Chavasse, Oxford and Liverpool; J. E. Clark, Guy's; M. C. Clark, Royal Free; E. C. Cline and R. Curle, Guy's; R. M. Dannatt, St. Bartholomew's; E. I. Davies, Cardiff and Charing Cross; L. ap I. Davies, University College; T. H. Edey and C. H. Edwards, Guy's; M. Fahmy, Cairo and London; N. Fahmy, Cairo and King's College; R. C. Fairbairn, Oxford and St. Bartholomew's; A. M. C. Forster, Royal Free; S. C. Ghose, Calcutta and St. Mary's; O. Gleeson, Westminster; B. H. Greensill, Birmingham; W. T. Gwynne-Jones, London; G. Habgood, Cambridge and London; G. H. Haines, University College; S. A. Hall and C. E. Harrison, Middlesex; H. S. Hensman, Madras and London; W. Hillbrook, Cambridge and St. George's; R. W. Hodgson-Jones, Manchester; R. A. Holmes, Guy's; G. J. P. Huddleston, Birmingham and University College; S. Hutchinson, University College; S. W. Isaacs, St. Bartholomew's; G. M. Jackson, Bristol; V. C. James, Middlesex; H. C. Jennings, St. Thomas's; R. B. John, Cardiff and Westminster; D. R. Jones, Guy's; D. P. Karaka, Bombay and London; C. H. Keay, Durham; N. E. Kendall, Guy's; J. S. Kennedy, Cambridge and St. George's; R. D. Langdale-Kelham, University College; E. E. D. Lau, Durham; C. G. Learoyd, St. Thomas's; J. S. Leslie, London; P. K. Liang, Cambridge and London; G. S. B. Long, Guy's; M. L. Loveless and W. B. Loveless, Middlesex; H. J. McCurrich, Bristol and St. Bartholomew's; A. J. V. McDonnell, London; A. McInnis, Toronto and London; W. G. McKenzie, Bristol; J. E. C. Maguire, St. Bartholomew's; G. Mallya, Madras and St. Bartholomew's; A. H. Manfield, London; C. J. Marshall, Charing Cross; R. G. Michelmore, London; D. C. Ogilvie, Middlesex; W. L. Partridge, Guy's; S. V. P. Pill, St. Mary's; C. L. G. Powell, St. Thomas's; R. A. W. Procter, Cambridge and St. Thomas's; A. L. Punch, Guy's; R. W. Rammell and C. R. Reckitt, London; A. E. Richmond, St. Thomas's; E. S. Rowbotham, Charing Cross; J. T. Samuel, University College; C. H. Savory, Cambridge and St. Bartholomew's; H. M. Scarborough, Royal Free; E. H. S. Scarr, Manchester; N. A. Scott, St. Bartholomew's; J. M. Shah, Bombay and St. Bartholomew's; T. W. Sheldon, Cambridge and Guy's; S. Simons, Cardiff and St. Mary's; T. H. Somervell, Cambridge and University College; H. G. Sparrow, St. George's and Durham; G. S. Stathers, Cambridge and St. Bartholomew's; R. G. Sterling, London; J. G. Stevens and A. H. Taymour, Guy's; R. C. Thomas, Cardiff and Westminster; A. P. Thomson, Birmingham; J. R. Tibbles, Aberdeen and London; E. Underhill, Birmingham; J. E. A. Underwood, University College; S. K. Vaidya, London; H. C. Viehoff, Liverpool; T. T. B. Watson, London; E. S. White, Bristol; C. M. Williams, Cardiff and St. Mary's; and G. R. C. Wilson, St. Thomas's.

Surgery.—A. C. Ainsley and C. G. Ainsworth, Cambridge and London; D. R. Alexander, St. Mary's, W. G. E. Allen, St. Bartholomew's; D. W. J. Andrews, Middlesex; F. L. Apperly, Oxford and Dublin; J. H. Bayley, London; C. M. Brophy, University College; J. B. Cavenagh, Oxford and St. Thomas's; J. K. J. Chambry, Amsterdam and St. Mary's; F. B. Chavasse, Oxford and Liverpool; P. Cheal, London; Y. J. Cieh, St. Thomas's; V. M. Coates, Cambridge and Bristol; H. M. Collins, London; W. L. Cox, Middlesex; R. Curle, Guy's; E. I. Davies, Cardiff and Charing Cross; J. K. Davies, St. Bartholomew's; W. A. Easton and C. H. Edwards, Guy's; H. H. L. Ellison, St. Bartholomew's; I. Feldman, jun., London; I. Feldman, sen., London; F. J. Folinsbee, Western University; A. M. C. Forster and C. I. Fox, Royal Free; G. C. Gell, Middlesex; C. C. G. Gibson, Guy's; B. Graves, Charing Cross; G. D. Gripper and H. S. Groves, Guy's; G. Habgood, Cambridge and London; S. A. Hall, Middlesex; R. Hargreaves, University College; R. C. Hewitt, Cambridge and St. Thomas's; R. A. Holmes, Guy's; H. R. W. Husbands and G. M. Jackson, Bristol; L. G. Jacob, Cambridge and London; R. B. John, Cardiff and Westminster; C. H. Keay, Durham; N. E. Kendall, Guy's; J. B. Leather, Cambridge and Birmingham; S. J. L. Lindeman, St. Bartholomew's; H. J. McCurrich, Bristol and St. Bartholomew's; A. J. V. McDonnell, London; J. B. McFarland, St. Bartholomew's; S. Mallinick, Halle and London; C. J. Marshall, Charing Cross; R. P. S. Mason, Middlesex; B. Mitra, Calcutta and Guy's; A. H. Morley and C. G. T. Mosse, London; N. F Norman, St. Bartholomew's; D. C. Ogilvie, Middlesex; T. Owen, Cambridge and St. Bartholomew's; C. F. O. Pandithesekere, Ceylon and Middlesex; O. Parry-Jones, London; E. W. Paul, Calcutta and Royal Free; E. C. Peers, Guy's; W. S. J. Peiris, Ceylon and London; L. D. Phillips, University College; H. D. Pickles, Leeds; R. F. Pinson, Birmingham; G. W. Pool, C. L. G. Powell, and T. L. Price, St. Thomas's; D. O. Richards, Guy's; A. E. Richmond, St. Thomas's; R. M. Riggall, Manchester; A. I. Rihan, St. Bartholomew's; G. W. R. Rudkin, University College; S. K. Sanyal, London; F. J. P. Saunders, Cambridge and St. Thomas's; C. H. Savory, Cambridge and St. Bartholomew's; H. M. Scarborough and E. A. Shaw, Royal Free; J. G. B. Smith, St. Bartholomew's; J. A. B. Snell, Cambridge and University College; T. H. Somervell, University College; H. G. Sparrow, St. George's and Durham; G. S. Stathers, Cambridge and St. Bartholomew's; R. G. Sterling, London; D. P. Thomas, St. Bartholomew's; D. C. Thomas, St. Thomas's; R. C. Thomas, Cardiff and Westminster; H. Q. F. Thompson, Guy's; R. R. Thomson, London; A. P. Thomson, Birmingham; J. R. Tibbles, Aberdeen and London; E. J. Tyrrell, Durham; J. E. A. Underwood, University College; W. E. Wade, Charing Cross; P. Wallice, Cambridge and London; M. J. T. Wallis, Guy's; A. H. Warde, St. Thomas's; A. R. S. Warden, Cambridge and St. Thomas's; K. J. F. Westman, Guy's; E. S. White, Bristol; B. Whitehead, St. Bartholomew's; H. A. B. Whitelocke, Oxford and King's College; G. L. Wilkinson, Birmingham; J. D. Wilkinson, St. Thomas's; C. M. Williams, Cardiff and St. Mary's; W. B. Wilson, St. Bartholomew's; G. W. Woodhouse, St. Thomas's.

Midwifery.—A. Z. Abushady, Cairo and St. George's; J. S. Alexander, University College; W. G. E. Allen, St. Bartholomew's; H. K. Alton, Royal Free; P. W. L. Andrew, Middlesex; J. Aydon, Cambridge and St. Bartholomew's; R. T. Bailey, Charing Cross; G. C. G. Baldini, St. Bartholomew's; E. G. Barker, St. Mary's; J. V. Bates, Cambridge and University College; K. L. Bates, Guy's; J. J. O. Beven, Cambridge and Middlesex; K. S. Bhat, Madras and St. Bartholomew's; E. Biddle, Cardiff and Guy's; J. A. Binning, University College; D. A. Blount, St. Bartholomew's; H. F. Brice-Smith, Cambridge and Middlesex; J. Brooks, Manchester; C. M. Brophy, University College; I. F. Buckle, Royal Free; A. S. Carter, Middlesex; L. A. Celestin, University College; M. Chadwick, Cambridge and Guy's; F. B. Chavasse, Oxford and Liverpool; G. E. Chissell, Middlesex; H. M. Cohen, Manchester; S. J. Cowell, Cambridge and University College; E. S. Cuthbert, St. Bartholomew's; E. I. Davies, Cardiff and Charing Cross; R. O. Eades, University College; N. G. El-Gawly, Cairo and St. Bartholomew's; H. Ellis, St. George's; W. J. Evans, Cardiff and University College; R. C. Fairbairn, Oxford and St. Bartholomew's; R. K. Ford, London; A. M. C. Forster, Royal Free; H. Gardiner-Hill, Cambridge and St. Thomas's; P. C. Gibson, London; G. T. Gimlette, St. Thomas's; O. Gleeson, Westminster; E. A. Green and F. H. S. Greenish, Cambridge and London; G. H. Haines, University College; H. W. Hales, Cambridge and St. Bartholomew's; R. C. Hewitt, Cambridge and St. Thomas's; R. B. Hick, St. Mary's; F. E. Higgins, Cambridge and St. Thomas's; N. H. Hill, St. Bartholomew's; R. W. Hodgson-Jones, Manchester; L. S. Holmwood, Cambridge and Middlesex; H. L. G. Hughes, University College; S. C. W. Iredale, St. Bartholomew's; G. M. Jackson, Bristol; L. G. Jacob, Cambridge and London; V. C. James, Middlesex; H. C. Jennings, St. Thomas's; R. B. John, Cardiff and Westminster; L. P. Johns, King's College; C. S. J. Kearney, St. Bartholomew's; C. H. Keay, Durham; F. A. Knott, Guy's; R. D. Langdale-Kelham, University College; M. E. A. Latif, Cairo and Middlesex; E. E. D. Lau, Durham; J. B. Leather, Cambridge and Birmingham; J. C. Lee, McGill; S. J. L. Lindeman, St. Bartholomew's; G. C. Linder, St. Bartholomew's; E. M. Litchfield, New Zealand and Guy's; V. E. Lloyd, Guy's; M. L. Loveless and W. B. Loveless, Middlesex; H. J. McCurrich, Bristol and St. Bartholomew's; W. G. McKenzie, Bristol; S. A. S. Malkin, University College; C. J. Marshall and G. S. Marshall, Charing Cross; B. R. L. Mayman, King's College; F. Mohamed, Cairo and Westminster; F. Molina, St. Thomas's; A. H. Morley, London; I. Mortada, Cambridge and University College; J. K. Muir, Middlesex; N. S. Nairne, St. Thomas's; F. W. Noble, Aberdeen and Middlesex; H. M. Oddy, Oxford and St. Thomas's; T. Owen, Cambridge and St. Bartholomew's; L. G. Phillips, Middlesex; H. D. Pickles, Leeds; R. F. Pinson, Birmingham; A. E. A. Poulier, Ceylon and Middlesex; E. A. Prichard-Evans, Middlesex; R. A. W. Procter, Cambridge and St. Thomas's; J. N. Puri, London; K. N. Purkis, Guy's; G. J. Randell, Cardiff and Westminster; H. Ratnarajah, Ceylon and St. Mary's; T. H. Rhys, Cardiff and Charing Cross; E. D. Richardson, Charing Cross; R. L. Robinson, University College; L. C. S. Roche, St. Thomas's; S. K. Sanyal, London; F. J. P. Saunders, Cambridge and St. Thomas's; C. H. Savory, Cambridge and St. Bartholomew's; N. A. Scott, St. Bartholomew's; W. W. S. Sharpe, St. Mary's; E. G. Sherwood, Royal Free; R. Sinha, Punjab and London; T. H. Somervell, Cambridge and University College; H. G. Sparrow, St. George's and Durham; G. S. Stathers, St. Bartholomew's; R. Stowers, University College; R. F. Sturridge, Middlesex; T. C. Summers, London; T. J. Taunton, St. Bartholomew's; R. R. H. O. Tha, Cambridge and University College; J. W. T. Thomas, Cardiff and Middlesex; W. L. Thomas, Middlesex; R. R. Thompson, London; I. S. Tirard, Cambridge and King's College; R. S. Topham, Leeds; E. J. Tyrrell, Durham; E. Underhill, Birmingham; H. J. Wallace, University College; H. J. Wallace, Royal Free; A. A. Watkinson, Charing Cross; J. W. Wayte, St. Thomas's; E. S. White, Bristol: E. M. White, Royal Free; W. R. White-Cooper, St. Bartholomew's; H. Whyte, London; N. J. Wigram, Sheffield; C. M. Williams, Cardiff and St. Mary's; G. R. C. Wilson, St. Thomas's; and G. C. N. Younger, Middlesex.

VICTORIA UNIVERSITY OF MANCHESTER.—At the Final M.B. and Ch.B. examination, held recently, the following candidates were successful:—

J. C. Bramwell and J. E. Brooks.

Obstetrics and Surgery.—S. G. J. Dowling.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.—The sixty-seventh annual report of this institution shows a reduced income and a larger expenditure for the year 1914 as a result of the war. Fortunately, however, substantial legacies have been received by the hospital during the past two years. For the year under notice 162 beds were in daily occupation, the average length of stay of each patient being nearly ten weeks. The number of new cases registered in the out-patient department was 7473, the total number of attendances being 31,193. With the report is included the reproduction of a scroll commemorative of the foundation-stone laying, a coloured picture of the grounds of the hospital, and illustrations of different departments of the institution.

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 39 cases were considered and grants amounting to £365 10*s.* were voted to 35 of the applicants. The following is a summary of the cases relieved:—

Daughter, aged 59, of M.R.C.S. Eng. who practised at Long Sutton. Had worked as governess and housekeeper for many years, but owing to recent death of employer is now out of employment. Only income an investment bringing in £5 per annum, and age against obtaining fresh situation. Voted £12 in 12 instalments.—Daughter, aged 45, of M.R.C.S. who practised at Burgh le Marsh. Lives with mother who has only a very small income. Applicant earned living as a teacher of music until the war commenced, but practically all her pupils have now given up. Voted £10, and referred to the Professional Classes War Relief Council.—Widow, aged 40, of M.B., Ch.M. Aberd. who died in 1914 and who practised at Manchester. Applicant left with seven children, ages 3 to 14 years, one son suffering from spinal disease. Only income a little from the sale of the practice. Requires help for the education of the children. Voted £5 and referred to the Guild.—Daughter, aged 57, of M.D. who practised at Kirkdale. Had earned a living at dressmaking until health became bad. Rent is paid by friends, but no income at present. Voted £12 in 12 instalments.—Widow, aged 44, of M.B., C.M. Glasg. who practised at Lenton and died in 1914 after a long illness, and was unable to provide for his widow. Earns a little, a collector for a society, but not sufficient to keep her. Two children, 10 and 12. Voted £10 in two instalments.—Wife, aged 53, of M.R.C.S. Eng. who practised at Retford, but is now totally incapacitated from work and is in a home. One son, who is being educated by a relative. Only certain income £8 per annum. Voted £5, with leave to apply again and referred to the Guild for report.—Daughter, aged 68, of L.S.A. who practised at Christchurch. Has earned a living as an artist, but owing to failing eyesight unable to follow her profession and sell the few pictures she has on hand. Voted £18 in 12 instalments.—Widow, aged 42, of L.S.A. who died this year and had practised at Padstow. Husband was ill with general paralysis for four years before death. Has tried to keep her home together for some time by taking in boarders, but has had none since the war commenced. One daughter, who is being educated at St. Ann's School. Voted £10.—Daughter, aged 33, of M.R.C.S. Eng. who practised at Whitechapel. Lives with mother, who has an Epsom pension. Applicant worked in one situation for many years, but has been discharged owing to war. Wants help to be trained as midwife. Training to be provided free, but outfit required. Appointment promised at end of training. Voted £12 through the Guild.—Daughter, aged 60, of M.R.C.S. Eng. who practised at Leeds. Applicant lives with her mother, who is a confirmed invalid. Lost all her capital in the Franklin frauds. Only income about £6 10*s.* per annum, and help from the Guild and the Fund. Previous help three times, £36. Voted £12 in 12 instalments.—Daughter, aged 53, of M.R.C.S. Eng. who practised at Rickmansworth. Suffering from arthritis and fibrosis. Only income £39 per annum from a relative. Quite unable to work. Relieved twice, £20. Voted £10 in two instalments.—Daughter, aged 58, of M.R.C.S. Eng. who practised at Peckham. Health very bad indeed. Only income £19 per annum from a sister. Relieved 17 times, £197. Voted £12 in 12 instalments.—Widow, aged 59, of M.R.C.S. Eng. who practised at Maida Vale. Was left entirely without means and suffering from chronic rheumatism and weak heart. Relieved 12 times, £118. Voted £15 in 12 instalments.—Daughter, aged 68, of M.R.C.S. Eng. who practised at Cranbrook. Very delicate and requires someone to look after her. Has an annuity from another benevolent fund, but not sufficient to maintain herself. Relieved 16 times, £168. Voted £12 in 12 instalments.—Widow, aged 45, of M.B., C.M. Edin. who practised at Ballindallock. Left totally unprovided for at husband's death in 1910. Has four children, three of whom are at school. Tries to earn a little by letting rooms, but has been unsuccessful lately. Relieved four times, £40. Voted £10 in two instalments.—Widow, aged 67, of M.R.C.S. Eng. who practised at Sheffield. Has made a little by teaching German in private schools, but cannot obtain any work at present. Has an Epsom pension. Relieved 15 times, £112. Voted £10 in two instalments.—Daughter, aged 59, of M.R.C.S. Eng. who practised at Blackheath. Has suffered since childhood with a nervous complaint, and never been able to work. Her sister helps as much as possible. Relieved 10 times, £91. Voted £10 in two instalments.—Widow, aged 84, of M.R.C.S. Eng. who practised at Great Marlow. Has three daughters, two of whom, along with one son, are deaf and dumb. None are able to earn much, and all live at home. Relieved 12 times, £80. Voted £18 in 12 instalments.—Widow, aged 60, of M.R.C.S. Eng. who practised at North Shields. Has five sons, three of whom have joined the army; consequently her income is very much reduced. One son too ill to work and the other abroad unable to help. Relieved once, £5. Voted £15, and advised to apply to the National Relief Fund.—M.D. of Dublin, aged 81, single, who practised in Lancashire. Old age prevents him from following his professional work. Has an Epsom pension. Relieved once, £18. Voted £18 in 12 instalments.—M.R.C.S. Eng., aged 77, a widower, who practised at Rainham. Gets a little locum work occasionally, but health and age will not allow him to do much. Relieved once, £18. Voted £18 in 12 instalments.—Widow, aged 60, of L.F.P.S. Glasg. who practised at Rothesay. Endeavours to obtain a living by letting rooms, but at present has none let. Suffers from rheumatism. Has a pension of £12. Relieved once, £12. Voted £12 in 12 instalments.—Daughter, aged 74, of M.D. who practised at Leominster. Has no income and is an inmate of a home for incurables. Requires a little help for clothes and a few necessary comforts. Was an annuitant of the Fund until she went into the home. Relieved 17 times, £209. Voted £6 in 12 instalments.—Widow, aged 56, of L.R.C.P. Edin. who practised at Blackburn. Earns a little by the day nursing children; health not good. Has one daughter who is now beginning to earn a little as a shop assistant. Relieved once, £12. Voted £12 in 12 instalments.—Daughter, aged 60, of M.D. Edin. who practised in London. Suffering from varicose veins and only able to earn very little by sewing. Lives with a sister who has also been helped by the Fund. Relieved nine times, £50. Voted £12 in 12 instalments.—Widow, aged 64, of M.R.C.S. Eng. who practised at Streatham. Only income £40 per annum; has an invalid daughter and other children unable to help. Too old and not strong enough to work. Relieved once, £12. Voted £12 in 12 instalments.—Daughter, aged 53, of M.R.C.S. Eng. who practised at Newport, Mon.

Applicant is blind, and recently has had an internal operation. Income only a few pounds a year from other charities. Relieved four times, £48. Voted £12 in 12 instalments.—Widow, aged 52, of M.B. Aberd. who practised in Warwickshire and Australia. Has been confined to her bed with severe illness for some months. Children only able to help very slightly; also obtains a little help from sister, but not sufficient to provide necessities. Relieved seven times, £73. Voted £12 in 12 instalments.—Widow, aged 75, of L.R.C.P. Edin. who practised at Birmingham. Has recently met with an accident, and has had to obtain help in the home. Has eight children, two of whom live at home but only able to contribute 10*s.* each week, and the other children married, and only able to give very little. Relieved three times, £30. Voted £18 in 12 instalments.—Emergency grants amounting to £15 10*s.* were also given to six applicants, and their cases were deferred for future consideration.—Four vacancies of £20 each among the annuities were also filled at this meeting.

The grants detailed above involve the Fund in an expenditure of £365 10*s.*, to meet which there is only an available balance of £49. The claims on the Fund arising out of the war are increasing month by month, but the resources show a decrease. Immediate support is essential unless the reserves are to be seriously depleted. Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, London, W.

USE OF PRESERVATIVES IN CREAM: APPEAL TO THE LOCAL GOVERNMENT BOARD.—With the view of putting pressure on the Local Government Board to secure the appointment of the long-promised Departmental Committee to consider the question of a standard quantity of preservative to be used in cream, the coöperation of Mr. Mead, the Marlborough-street police-court magistrate, has been secured by Mr. F. W. Beck, who represented the defendants at the hearing of summonses against two dairymen at the court recently. Proceedings were instituted by the Westminster City Council against Champion's Dairy, Limited, for having on March 1st sold preserved cream mixed with a preparation of boric acid equivalent to 0·42 per cent.—i.e., 29 grains per pound of crystallised boric acid, so as to render it injurious to health; and against David John Morgan, trading as J. Morgan and Son, for having on Feb. 17th sold preserved cream mixed with 0·40 per cent. by weight of boric acid (H_3BO_3) equivalent to 28 grains of boric acid per pound of cream, so as to render it injurious to health. Mr. Rotten represented the council. Mr. Beck, on the case of Champion's Dairy being called, said the magistrate would remember that these summonses had been adjourned in order that he might communicate with the Local Government Board his worship's intention to proceed that day with the hearing. He had communicated with the Local Government Board accordingly, and had received a reply that it was contrary to their practice to intervene in cases which were the subject of proceedings, at the same time referring him to a reply by the President to a question in the House of Commons in which he said that in consequence of the war it had been impossible to proceed with the appointment of the promised Departmental Committee, that there was difference of opinion as to the use of preservatives, but that it was inadvisable under present circumstances for authorities to institute proceedings. In view of that answer he suggested that Mr. Mead should adjourn the summonses *sine die*, thus following the course pursued by his colleagues in other metropolitan courts. In support also of his proposal he mentioned that 17 summonses issued against other defendants by the Westminster City Council had already been adjourned with the consent of Mr. Rotten. Mr. Mead decided to adjourn the summonses for two months, and in the meantime to intimate to the President of the Local Government Board that he considered it most urgent that the Board should fix a standard as speedily as possible, as not only the authorities and the trade but also the magistrates experienced great difficulty in dealing with the matter.

MEDICAL SOCIETY OF LONDON.—The general meeting for the election of officers and council will take place on Monday next, May 10th, at 8 P.M. Mr. D'Arcy Power will give a short demonstration, illustrated by the epidiascope, on Early Books on Naval and Military Surgery from the society's library. After the meeting a selection of some of the society's old and rare medical works will be on exhibition. Owing to the absence of Sir William Osler on military service the annual oration and conversazione fixed for May 17th will not take place.

POOR-LAW MEDICAL OFFICERS' ASSOCIATION.—A council meeting was held on April 27th, Surgeon-General G. J. H. Evatt, the President, being in the chair. Dr. Major Greenwood, honorary secretary, reported the action taken on the attempt of the Paddington guardians to appoint, subject to a determination of office at three months' notice, a district medical officer residing in the district. A letter was addressed to the Local Government Board in November drawing attention to this as an infringement of the Medical Appointments Order (the reason given by the board being their desire, at an opportune time in the future, to organise their medical relief after the manner of the Bermondsey guardians), and urging the Local Government Board to refuse consent, unless a proper scheme were laid before them. The Local Government Board had finally given consent to the appointment of a district medical officer, but only for a limited period. If at the end of the time the guardians had no scheme ready they would be required to appoint a medical officer in accordance with the Medical Appointments Order. Had the Paddington guardians been permitted to appoint a medical officer for an indefinite time, subject to a three months' notice, the security of tenure of all district medical officers would have been seriously threatened. The honorary secretary was directed to watch carefully any further developments in the Paddington union. A letter was read from Dr. E. R. Fothergill *re* the Federation of Medical Societies with the British Medical Association. It was unanimously agreed that some kind of federation was desirable, but that any concrete scheme must be examined very closely. Independence was needful for the Poor-law Medical Officers' Association, and hitherto they had endeavoured to work as much as possible in conjunction with the Public Health and Poor-law Committee of the British Medical Association. The financial bearing also was important, as present subscriptions were really inadequate for their present work. Letters were then considered from Dr. A. Drury (Halifax) dealing with important Poor-law questions: (1) As to the right of a lady visitor to order the attendance of a medical officer; (2) whether it was part of the duty of a medical officer to diagnose refraction and prescribe spectacles; (3) whether a lady visitor could demand a report on a case from the medical officer; and (4) whether the clerk could require of a medical officer a report as to the sanitary condition of a house. The council answered all these questions in the negative, adding with regard to (4) that while the medical officer ought to draw the attention of the guardians to any serious sanitary defect that interfered with proper attention to a Poor-law patient, the general sanitary state of the house should be reported on by the medical officer of health. The council unanimously confirmed the appointment of the honorary secretary, Dr. Major Greenwood, to act as their representative on the Council for District Nursing. The honorary secretary said that the report of the Association on the Poor-law Institutions Order, 1913, had been considered by the Public Health Committee of the British Medical Association, and on their recommendation had been endorsed by the central council. In regard to the situation of Poor-law medical relief at Burnley a letter was read from Dr. A. P. Agnew, in which it was stated that on April 9th, at a meeting of the Burnley Division of the British Medical Association, a resolution was passed that no member should accept a post as district medical officer under the guardians in the existing conditions. The profession refused to consider any setttlement till the late public vaccinators were reinstated, and then the other difficulty seemed insuperable. The council thought it was a matter for a Local Government Board inquiry. The honorary secretary was directed to ask Dr. Agnew to furnish any instance of neglect or deficient attendance on Poor-law patients. The council then considered complaints of Poor-law medical officers employed on military duties that they did not receive the same consideration as was given to other civilian practitioners. The following resolutions were unanimously carried:—

1. That in all cases where military duties are discharged by Poor-law medical officers the salaries paid to whole-time officers should be on a scale not less than that paid by the War Office to members of the Royal Army Medical Corps discharging similar duties.

2. That where the duties are part-time only, an addition should be made to the medical officer's salary in proportion to the extra labour involved.

It was decided that the annual meeting should be held early in July, preceded by a council meeting, and that only formal or urgent business should be transacted.

ROYAL INSTITUTION.—The annual meeting of the members of the Royal Institution was held on May 1st, Sir James Crichton-Browne, Treasurer and Vice-President, being in the chair. The annual report of the committee of visitors for the year 1914, testifying to the continued prosperity and efficient management of the institution, was read and adopted. The report of the Davy Faraday Research Laboratory committee was read. Forty-four new members were elected in 1914. Sixty-two lectures and 19 evening discourses were delivered in 1914. The books and pamphlets presented amounted to about 338 volumes, making with 652 volumes (including periodicals bound) purchased by the managers, a total of 990 volumes added to the library in the year. Thanks were voted to the president, treasurer, and secretary, to the committees of managers and visitors, and to the professors, for their valuable services to the institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—President: The Duke of Northumberland. Treasurer: Sir James Crichton-Browne. Secretary: *Colonel Edmond H. Hills. Managers: *Sir Thomas Barlow, Dr. Horace T. Brown, *Dr. J. H. Balfour Browne, Dr. Andrew Carnegie, Mr. Charles Edward Groves, Sir Robert Hadfield, *Mr. Charles Hawksley, the Hon. Richard C. Parsons, *Mr. Edward Pollock, *Sir James Reid, Lord Rothschild, Mr. Alexander Siemens, Mr. Alan A. Campbell Swinton, Mr. Harold Swithinbank, and *Lord Wrenbury. Visitors: Rev. Edward S. Dewick, Lieutenant-Colonel Henry E. Gaulter, Mr. Joseph G. Gordon, Dr. William J. Gow, Dr. J. Dundas Grant, Mr. John W. Jarvis, Mr. James Y. Johnson, Mr. H. R. Kempe, Mr. Francis Legge, Mr. Francis K. McClean, Mr. Ernest R. Moon, Mr. Richard Pearce, Mr. Henry G. Plimmer, Mr. Arthur J. Walter, and Sir Henry J. Wood. At a general meeting held on Monday last, May 3rd, the Duke of Northumberland, K.G., the President, in the chair, special thanks were returned to Dr. Thomas Dewar for a donation of £15 15*s.* to the Fund for the Promotion of Experimental Research at Low Temperature. The managers whose names above are marked with an asterisk were elected vice-presidents.

NORFOLK AND NORWICH HOSPITAL.—The report of the board of management of this hospital for the year 1914 records a deficit of £1857 10*s.* 8*d.* The total income was £12,429 6*s.* 9*d.* and the total expenditure £14,286 17*s.* 5*d.* Without encroaching on the ordinary accommodation of the hospital, provision was made for the treatment of the sick and wounded from the seat of war. 937 men were received up to Dec. 31st, 1914. Since that time further accommodation has been provided.

Her Majesty the Queen has sent £250 to the London (Royal Free Hospital) School of Medicine for Women to pay for the training and expenses of a woman medical student. The money formed part of a fund placed at the disposal of the Queen by the wives of Freemasons. The council will make known shortly the conditions for the award of the Queen's gift.

ROYAL SANITARY INSTITUTE. — A sessional meeting of the institute will be held in the Guildhall, Shrewsbury, on Friday, May 28th, when a discussion on the Value of Mechanical Filters in the Purification of Water will be opened by Dr. Thomas Orr, medical officer of health of Shrewsbury. On Saturday, May 29th, visits will be made to Shrewsbury Housing Scheme, Ditherington; Mechanical Filters, Chester-street; and the Public Abattoir.

A GOLDEN WEDDING.—Mr. Alfred Grace, M.R.C.S., L.S.A., of Chipping Sodbury, Gloucestershire, a brother of Mr. W. G. Grace, celebrated the fiftieth anniversary of his wedding on April 26th, and received the congratulations of his friends and patients. Mr. Grace, like his brother, has been a noted sportsman, but his keenness for hunting eclipsed his interest in cricket.

A CENTENARIAN.—Rachel Case, of Wootton Fitzpaine, near Charmouth, has recently died in her 101st year.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Government and the Drink Problem.

PARLIAMENT has now been informed of the measures which the Government propose as a means of checking the excessive consumption of alcoholic beverages in war time, particularly in districts where munitions of war are being produced. The scheme is twofold—control of the licensed trade in the munition areas, and heavy additional taxation on beer and spirits. The necessary Parliamentary powers to enable the control to be exercised is taken by the Defence of the Realm (Amendment No. 3) Bill, which was introduced by the Chancellor of the Exchequer in the House of Commons on Thursday, April 29th. That control goes the length of having power to close any public-house, the presence of which for the moment is considered injurious. On the same evening resolutions were passed in Committee of Ways and Means for the purpose of imposing very heavy additional taxation upon spirits and also upon beers containing more than 7 per cent. of proof spirit. The duty upon spirits is practically doubled, the surtax being at the rate of 14*s.* 9*d.* per gallon. In the original resolution submitted to the House it was proposed that a proportionate increase of duty should be imposed on the following articles in which spirit is contained, or in the manufacture of which spirit is used—chloral hydrate, chloroform, collodion, ether acetic, ether butyric, ether sulphuric, iodide of ethyl, ethyl bromide and ethyl chloride. These articles were, however, omitted from the resolution imposing the surtax, on the motion of the Attorney-General. The wine duty is quadrupled and an additional charge of 15*s.* put on sparkling wine in bottle. The additional duties on the heavier beers are on a sliding scale which is as follows:—For every 36 gallons of beer brewed at a gravity of more than 43° and not exceeding 48°, 12*s.*; of more than 48° and not exceeding 53°, £1 4*s.*; of 53° and over, £1 16*s.*

These resolutions had provisional effect as soon as they were passed, but in order that a more permanent character should be given to them they require to be embodied in a Finance Act.

A good deal of criticism has been made of the Government proposals to place heavy taxes on beer and spirits. The Chancellor of the Exchequer has been meeting deputations from the licensed trade, and the opinion is strongly held at Westminster that considerable modifications in the scale of the duties will be made. But the whole subject at present is under negotiation.

Local Government Board Report.

The forty-third annual report of the Local Government Board (Part III.) for the year 1913–14 has been issued as a Parliamentary Blue-book. It deals with public health and local administration.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 28TH.

Vaccination in the Central Provinces.

Mr. SNOWDEN asked the Under Secretary of State for India whether it was proposed to introduce legislation into the Central Provinces for the enforcement of vaccination; and, if so, whether a conscience clause would be introduced into the Vaccination Act, as in the case of the English and Scotch Vaccination Acts of 1907.—Mr. CHARLES ROBERTS replied: Compulsory vaccination is already enforceable in municipalities at the request of the municipal commissioners and cantonments in the Central Provinces under an Act of 1880. An amending Bill is now proposed extending the power of enforcing compulsory vaccination to certain quasi-municipal areas. It is specified both in the Act and in the amending Bill that it is open to any inhabitant of the area to object to the extension, but in neither case is there a conscience clause.

THURSDAY, APRIL 29TH.

Anti-Inoculation Leaflet.

Mr. RONALD MCNEILL asked the Under Secretary for War whether his attention had been called to the circulation by some person or persons unknown of a leaflet suggesting that a Territorial died last November, at Lytham, as the result of antityphoid inoculation, and that the death certificate falsely alleged a different cause of death; and whether he would take steps to prevent the dissemination of incitements to soldiers to endanger their own and their comrades' lives by refusing to undergo inoculation.—Mr. TENNANT said in reply: Reports have been received that this leaflet has been distributed both with and without the statement that the death was ascribed to a different cause on the death certificate. Such steps as were considered necessary have been taken.

Mr. McNEILL: Cannot the right honourable gentleman deal with this matter under the Defence of the Realm Act?—Mr. TENNANT: I am advised that proceedings could not be taken in this case. Therefore I am afraid that the answer to the honourable Member is in the negative. But if he likes to repeat the question I will give him a more definite reply.

Medical Officers of the Territorial Force.

Mr. FALLE asked the Under Secretary for War whether he was aware that all lieutenants, Royal Army Medical Corps, had recently been promoted to the rank and pay of captains, and whether a medical officer, however long his service, attached to a unit other than a medical unit could not attain higher rank than that of major, while *à la suite* medical officers, who were not attached to Territorial or other units before the war, started now as lieutenant-colonels, majors, and captains, and drew the pay of those ranks; that officers *à la suite* were, for the most part, able to remain in their own town and carry on their private practice without passing any examination for rank; whether he could see his way to grant all majors and captains of, say, five years' standing, attached before the war to Territorial or other units, the rank of lieutenant-colonel or major and the pay of those ranks; and would he remove the disadvantages as to promotion and pay now attaching to the medical officer who had served for years before the war attached to a Territorial or other unit.—Mr. TENNANT said in reply: The position of Territorial Force Royal Army Medical Corps officers in regard to promotion and pay is now under consideration.

Medical Attendance and Hospital Charges for Soldiers.

Mr. WING asked the Financial Secretary to the War Office whether the weekly charge for insurance covered all medical attendance and hospital charges for soldiers without further deductions.—Mr. TENNANT answered: No, sir. Medical attendance is free, but for hospital treatment a stoppage up to, but not exceeding, 7*d*. a day may be made if the officer commanding so decides.

Health of the New Troops in India.

Mr. SAMUEL SAMUEL asked the Under Secretary for India whether he could recommend his department to supply to the troops in India mosquito nets to prevent the sickness amongst the new troops going out and to ensure economy to the country in extra efficiency.—Mr. CHARLES ROBERTS replied: The provision of mosquito curtains has been sanctioned for all men of the Territorial Force who may have to serve on the plains in India in the coming summer.

Bovine Tuberculosis.

Sir JOHN SPEAR asked the Parliamentary Secretary to the Board of Agriculture how many bullocks suffering from tuberculosis were destroyed during the last complete year, and the amount of compensation paid to the owners of the animals.—Sir HARRY VERNEY answered: The number of bovine animals in respect of which notices of intended slaughter under the Tuberculosis Order, 1913, were received during the year ended June 30th, 1914, was 6651, but the actual number of animals slaughtered was probably less. Compensation is paid by the local authorities, and only in part refunded by the Board.

TUESDAY, MAY 4TH.

Enteric Fever in the Expeditionary Force.

Replying to Sir COURTENAY WARNER, Mr. TENNANT (Under Secretary for War) said: The latest information with regard to the incidence of enteric fever amongst the British troops in the Expeditionary Force is as follows. Up to date 963 cases have occurred. Of these, 780 have been analysed and 142 cases have occurred in men inoculated fully with two doses of vaccine. Amongst these 10 deaths have occurred, giving a case mortality of 7 per cent. 157 cases have occurred in men partially protected by inoculation—i.e., who have had only one dose of vaccine. Amongst these there have been 10 deaths, giving a case mortality of 6·36 per cent. 481 cases have occurred in uninoculated men. Amongst these there have been 100 deaths, giving a case mortality of 20·79 per cent. To appreciate the full value of these figures it must be brought to notice that 90 per cent. of the troops forming the Expeditionary Force have been inoculated voluntarily. Therefore, amongst 90 per cent. of the force—i.e., inoculated men—there have been 299 cases and 20 deaths. In the other 10 per cent.—i.e., uninoculated men—there have been 481 cases and 100 deaths.

Release of Medical Personnel.

Sir JOHN LONSDALE asked the Secretary of State for Foreign Affairs whether any agreement had yet been arrived at between the belligerent Powers in reference to the mutual release of medical personnel detained with prisoners of war in the respective countries.—Sir E. GREY replied: The answer is in the negative, and negotiations on the subject are still proceeding with the German Government through the United States Embassies in London and Berlin.

Medical Officers of the Territorial Force.

Sir CLEMENT KINLOCH-COOKE asked the Under Secretary for War whether he was aware that officers in the Territorial Force were excluded from obtaining increments of pay similar to those given to officers in the Regular Army; that a major in the Royal Army Medical Corps, Territorial Force, although having 10 years' service in the ranks, received 23*s*. 6*d*. a day, and must render three years' embodied service before being entitled to draw 26*s*.; and would he consider the advisability of removing what was regarded to be an injustice throughout the Territorial Force, and grant increments of pay to all ranks in respect of combined service rendered before and after embodiment.—Mr. TENNANT answered: Service in the Territorial Force before embodiment cannot be regarded as equivalent to continuous service in the Regulars, but the position of Territorial Force Royal Army Medical Corps officers with regard to pay and promotion is now receiving consideration.

The Use of Asphyxiating Gases in Warfare.

Mr. RONALD McNEILL asked the Under Secretary for War whether his attention had been called to a statement, made by the official eye-witness with the British Army at the front on April 6th, to the effect that it had been learnt from German prisoners that the enemy were preparing to asphyxiate our men by means of poisonous gas stored under pressure in steel cylinders; whether this form of attack was, in fact, adopted by the Germans on April 22nd; whether any, and what, steps had been taken in the interval to protect our men against the effects of poisonous gas; and whether it was intended to allow the enemy to pursue this mode of warfare without employing similar expedients against him, after due notice, by way of retaliation.—Mr. TENNANT said in reply: I regret to have to inform the honourable gentleman that, notwithstanding their engagements under the Hague Convention, the Germans have on more than one occasion used poisonous gases in the manner described and have caused the death of numbers of our men by poisoning. In spite of rumours to the contrary, it was not believed that any Power which had signed the Hague Convention could be guilty of so heinous a breach of its solemn undertaking as the violation of the fundamental principles of that agreement by the introduction into modern warfare of such a method as this which may have far-reaching results. The latter part of the question is under consideration.

The Production of Morphia.

Mr. THEODORE TAYLOR asked the President of the Board of Trade what were the total amounts and values of morphia manufactured in the United Kingdom in each of the years 1910, 1911, 1912, 1913, and 1914; what were the amounts and values exported to China, Japan, and Hong-Kong respectively; and whether any provisions were in operation to secure the limitation of its use to medical or other legitimate purposes.—Mr. RUNCIMAN said in reply: There are no available statistics of the production of morphia in the United Kingdom, but I will circulate with the votes a statement showing the exports of morphia to China, Japan, and Hong-Kong. His Majesty's Minister at Peking has reported that the Chinese Government have announced their intention of putting the International Opium Convention into force as from Feb. 11th last, but His Majesty's Government have no information as to the intentions of the Japanese Government in this respect or as to any regulations in force in either country as to the use of morphia. As regards Hong-Kong, I understand that the Pharmacy Ordinance of 1910 imposes certain restrictions on the importation and sale of morphine.

The following statement (circulated with the votes) shows the quantity and value of morphia and morphia salts exported and re-exported from the United Kingdom to the countries specified in each of the undermentioned years:—

		Quantity. Ozs.	Value. £.
To China	1911	15	9
	1912	—	—
	1913	2,270	1,080
	1914	2,329	900
To Japan	1911	58,352	24,071
	1912	125,907*	68,650*
	1913	252,110	118,794
	1914	352,130	143,975
To Hong-Kong	1911	17,200	6,347
	1912	—	—
	1913	640	320
	1914	—	—

* Includes 1600 ounces, valued at £800, of morphia, &c., of foreign or colonial origin.

Note.—The exports and re-exports of morphia and morphia salts were not separately recorded in the trade returns of the United Kingdom prior to Jan. 1st, 1911.

Scottish Undergraduates in the Army.

Mr. McCALLUM SCOTT asked the Secretary for Scotland whether he had considered the position of the students of Scottish Universities who were now serving in His Majesty's forces, and with regard to whom the universities had no power to modify their curricula; and whether he had received representations from any of the university courts with regard to this question.—Mr. McKINNON WOOD answered: I have received a representation from the Glasgow University Court on this subject, which is receiving consideration.

WEDNESDAY, MAY 5TH.

Consultant Surgeons for the Navy.

Commander BELLAIRS asked the Secretary to the Treasury whether he was aware that the Board of Admiralty made an arrangement during peace time with eight members of the Royal College of Surgeons under which these gentlemen were each drawing £5000 per annum, though the circumstances of the war had not up to now interfered with their private practice; and whether this total expenditure of £40,000 per annum was reviewed by the Treasury before it was sanctioned.—Mr. ACLAND answered: I understand that these appointments were made in the first instance under a general authority given by the Treasury in 1908 for the appointment in the event of the outbreak of war of consulting surgeons for hospital ships at a remuneration not then specified. On August 14th the Treasury were informed of the appointments, and also that for administrative reasons five distinguished surgeons and one physician (with remuneration at the rate of £5000 a year each) were being employed at the Royal Naval Hospitals instead of being sent out on hospital ships. Upon representations from the Admiralty that it was essential that the services of these specialists should be available at the respective hospitals for the performance of operations at a moment's notice, the Treasury sanctioned the arrangements which had been made. The total number of appointments at £5000 a year is six and not eight as stated in the question. As regards the conditions of employment I am informed by the Admiralty that five of the six reside at and are performing daily duties at Haslar, Plymouth, and Chatham, and the sixth has to visit and perform surgical work in all the naval and auxiliary hospitals in Scotland. In addition the five who are resident at the English hospitals visit for consulting purposes other hospitals in which naval sick and wounded are being treated. It is only in any casual spare time that private practice can be followed.

Spirit Taxes and the Manufacture of Medicine.

Mr. FOSTER asked the Chancellor of the Exchequer whether he proposed in the suggested increased taxation of spirits to include in such taxation spirit used in the manufacture of medicine.—Mr. LLOYD GEORGE wrote in reply: I am considering this matter. The Board of Customs and Excise are in communication with the Pharmaceutical Society.

BOOKS, ETC., RECEIVED.

ALLEN, GEORGE, AND UNWIN, LIMITED, London.
Perpetual Peace. By Immanuel Kant. Translated, with Introduction and Notes, by M. Campbell Smith, M.A., with Preface by Professor Latta. Price 2*s.* net.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

NASH, L. C., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer to the Shildon Urban District Council.

OVEREND, H. F., M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Irlam District of the county of Lancaster.

RIORDAN, WILLIAM, L.R.C.S. Irel., L.K.Q.C.P. Irel., has been appointed Medical Officer for the Clonmoyle Dispensary District.

TAYLOR, A. J. T., has been appointed Resident Physician at the Edinburgh Dispensary.

TIBBLES, SYDNEY G., Temporary Lieutenant, R.A.M.C., has been appointed Specialist in Ophthalmology to Devonport Military Hospital.

WIGAN, CHARLES ARTHUR, M.D. Durh., M.R.C.S., L.S.A., has been re-appointed Chairman to the Portishead (Somerset) District Council.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

ALTON, HANTS. LORD MAYOR TRELOAR CRIPPLES' HOSPITAL.—Two Assistant Resident Medical Officers. Salary as arranged, with board, residence, and laundry.

ANGLO-SERBIAN HOSPITAL, Urnjatchka, Benja, Serbia.—Surgeon.

BETHLEM ROYAL HOSPITAL, Lambeth-road, S.E.—Assistant Medical Officer, unmarried. Salary £275 per annum, with apartments, board, and laundry.

BIRKENHEAD BOROUGH HOSPITAL.—Female Senior and Junior House Surgeons. Salary £180 and £150 per annum respectively, with board and laundry.

BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, attendance, &c.

BIRMINGHAM, ROMSLEY HILL SANATORIUM FOR CONSUMPTIVES.—Assistant Resident Medical Officer, unmarried. Salary £250 per annum, with board, apartments, and laundry.

BOLTON INFIRMARY AND DISPENSARY.—Third House Surgeon. Salary £170 per annum, with apartments, board, and attendance.

BOURNEMOUTH, ROYAL VICTORIA AND WEST HANTS HOSPITAL.—House Surgeon for six months. Salary £100 per annum, with board, lodging, washing, &c.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.

BRIGHTON EDUCATION COMMITTEE.—Temporary Junior School Doctor. Salary at rate of £350 per annum.

BRISTOL, BEAUFORT WAR HOSPITAL.—Chief Resident Surgeon. Also Resident Physician and Surgeon.

BRISTOL GENERAL HOSPITAL.—Second House Physician, House Surgeon, Casualty House Surgeon, and Resident Obstetric Officer, all for six months. Salary at rate of £150 per annum, with board, residence, &c.

BRISTOL ROYAL INFIRMARY.—Throat, Nose, and Ear House Surgeon for six months. Salary at rate of £120 per annum, with board, apartments, and laundry.

BURNLEY UNION WORKHOUSE.—Resident Assistant Medical Officer or Locum Tenens. Salary £200 per annum, with apartments, rations, washing, and attendance.

BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £135 per annum, with residence, board, and washing.

BURY INFIRMARY.—Senior and Junior House Surgeons. Salary £175 and £150 per annum respectively, with board, residence, and washing.

Buxton, Derbyshire, Devonshire Hospital.—Assistant House Physician for six months. Salary £100 per annum, with apartments, board, and laundry.

Cardiff, King Edward VII.'s Hospital.—Resident Surgical Officer. Salary £160 per annum, with board, laundry, and apartments.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £200 per annum, with apartments (not board).

Carmarthen, Joint Counties Asylum.—Temporary Second Assistant Medical Officer. Salary at rate of £200 per annum, with board, lodging, washing, &c.

Cheshire County Council.—District Tuberculosis Officer. Salary £350 per annum.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—House Physician. Salary as agreed, with board, residence, and washing.

Croydon Borough Hospital.—Senior Resident Medical Officer and Bacteriologist. Salary £200 per annum, with board, residence, and washing. Also Assistant Resident Medical Officer. Salary £150 per annum, with board, residence, and laundry.

Croydon Union.—Assistant Medical Superintendent of Infirmary and Assistant Medical Officer of Workhouse and Childrens' Homes. Salary £225 per annum, with usual residential allowances.

Denbigh, North Wales Counties Asylum.—Second Assistant Medical Officer.Salary £220 per annum, with apartments, board, attendance, and washing.

Derby, Mickleover County Asylum.—Medical Superintendent. Salary £550 per annum, with house, laundry, &c.

Derbyshire Education Committee.—Temporary Female Assistant School Medical Officers. Salary £400 per annum, inclusive.

East Sussex County Council.—Female Inspector of Midwives and Child-Welfare. Salary £190 per annum.

Essex County.—Temporary Assistant Tuberculosis Officer. Salary at rate of £350 per annum.

Exeter City.—Assistant Medical Officer of Health and Assistant School Medical Officer. Salary £300 per annum.

Guildford, Royal Surrey County Hospital.—House Surgeon. Salary £150 per annum, with board, residence, and laundry.

Hemel Hempstead, Herts, West Herts Hospital.—Resident Medical Officer. Salary £150 per annum, with rooms, board, and washing.

Hospital for Consumption and Diseases of the Chest, Brompton.—House Physician for six months. Salary 30 guineas.

Hull Royal Infirmary.—House Physician, unmarried. Salary £105 per annum, with board and apartments. Also Assistant House Surgeon. Salary at rate of £100 per annum, with board and lodging. Also Casualty House Surgeon. Salary at rate of £80, with board and lodging.

Indian Medical Service.—Ten Commissions.

Inverness, Northern Infirmary.—House Surgeon. Salary £150 per annum, with board, &c.

Ipswich Borough Mental Hospital.—Resident Medical Superintendent. Salary £400 per annum, with residence, washing, &c.

Island of Sanday, Orkney.—Medical Practitioner and Vaccinator. Salary £100 per annum.

King Edward VII. Sanatorium, Midhurst, Sussex.—Second Assistant Medical Officer. Salary £150 per annum, with board, lodging, and attendance.

Leeds General Infirmary.—Resident Casualty Officer. Salary £125 per annum, with board, residence, and laundry.

Lochgoilhead and Kilmorich Parish.—Medical Officer and Vaccinator. Salary £100 per annum.

London Fever Hospital, Liverpool-road, N.—Assistant Resident Medical Officer. Salary £250 per annum, with residence and board.

Macclesfield, Cheshire County Asylum, Parkside.—Junior Assistant Medical Officer. Salary £250 per annum, with apartments, board, laundry, &c.

Manchester, Ancoats Hospital.—Two Residents.

Manchester Children's Hospital, Pendlebury.—Resident Medical Officer, unmarried, for six months. Salary at rate of £100 per annum.

Manchester Children's Hospital, Gartside-street. — Medical Officer. Salary £180 per annum.

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

Metropolitan Ear, Nose, and Throat Hospital, Fitzroy-square, W. Clinical Assistants.

Mile End Old Town Infirmary.—Assistant Medical Officer. Salary £275 per annum, with board, lodging, and washing.

Mount Vernon Hospital for Consumption and Diseases of the Chest, Northwood, Middlesex.—House Physician. Salary £150 per annum, with board, residence, and washing.

Newport Mental Hospital, Caerleon, Mon.—Temporary Assistant Medical Officer. Salary 5 guineas per week, with board, rooms, and attendance.

Norwich, 3rd Line Depôt, 2nd East Anglian Field Ambulance, Royal Army Medical Corps (Ter.).—Two Medical Officers. Pay and allowances as in Regular Army.

Nottingham Children's Hospital.—Female House Surgeon for six months. Salary at rate of £130 per annum, with apartments, board, and washing.

Oxford, Radcliffe Infirmary and County Hospital.—Honorary Surgeon.

Paddington Green Children's Hospital, W.—Temporary Surgeon in Charge of Out-patients.

Portsmouth Corporation Mental Hospital.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—Temporary Assistant Physician. Salary £25 per annum. Also Temporary Surgeon for Ear, Nose, and Throat Department. Salary £25 per annum.

Rotherham Hospital.—Junior House Surgeon. Salary £125 per annum, with board, lodging, and washing.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Resident Medical Officer.

St. Mary's Hospital for Women and Children, Plaistow, E.—Resident Medical Officer and Assistant Resident Medical Officer. Salary at rate of £110 and £90 per annum respectively, with board, residence, and laundry.

St. Pancras Dispensary, 39, Oakley-square, N.W.—Resident Medical Officer, unmarried. Salary £300 per annum, with residence and attendance.

Salisbury General Infirmary.—House Surgeon and Assistant House Surgeon, unmarried. Salary £100 and £75 per annum respectively, with apartments, board, lodging, and washing.

Sheffield Municipal Tuberculosis Dispensary.—Two Assistant Medical Officers. Salary £350 per annum.

Sheffield Royal Infirmary.—House Surgeon and Assistant House Physician. Salary £100 per annum, with board and residence.

Shrewsbury, Royal Salop Infirmary.—House Physician. Salary at rate of £110 per annum, with board and apartments.

Somerset County Education Committee.—School Oculist and Medical Inspector. Salary £350 per annum.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Female House Surgeon. Salary £150 per annum, with residence, board, and washing.

Taunton and Somerset Hospital, Taunton.—Senior House Surgeon. Salary £250 per annum, with board, lodging, and laundry.

Tiverton Hospital, Devon.—House Surgeon and Dispenser. Salary £80 per annum and all found.

Tunbridge Wells General Hospital.—House Surgeon, unmarried. Salary £100 per annum, with board, residence, &c.

Walsall and District Hospital.—Assistant House Surgeon and Anæsthetist. Salary £150 per annum, with board, residence, and laundry.

Warrington Infirmary and Dispensary.—Junior House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.

Warrington, Lord Derby War Hospital.—Resident Physician and Surgeon. Also Resident Pathologist and Bacteriologist.

West Bromwich and District Hospital.—House Surgeon and Assistant House Surgeon, unmarried. Salary £150 and £120 per annum respectively, with residence, board, and laundry.

West-End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, 73, Welbeck-street, W.—Clinical Assistants to Out-Patients' Physicians.

West Ham and Eastern General Hospital, Stratford, E.—House Physicians. Salary £120 and £100 per annum, with board, residence, and washing.

Whitechapel Dispensary for the Prevention of Consumption.—Temporary Medical Officer. Salary £500 per annum.

Wolverhampton and Staffordshire General Hospital.—Resident Medical Officer and House Surgeon for six months. Salary at rate of £150 per annum, with board, rooms, and laundry.

Worcester County and City Asylum.—Assistant Medical Officer. Salary £250 per annum, all found.

Worcester General Infirmary.—Resident Medical Officer. Salary £150 per annum, with board, residence, and washing.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Birtley, in the county of Durham ; and at Lurgan, in county Armagh.

Births, Marriages, and Deaths.

BIRTHS.

Davies.—On April 24th, at St. Olafs, Kingston-on-Thames, to Dr. and Mrs. H. R. Davies, a son.

Robertson.—On April 27th, at Clarence-drive, Hyndland, Glasgow, to Dr. and Mrs. Berkeley H. Robertson, a daughter.

Stewart.—On April 26th, at Pinewood, Beckenham, the wife of F. W. Stewart, M.D., of a daughter.

Woods.—On May 4th, at Waldemar-mansions, S.W., the wife of W. W. Woods, M.R.C.S., of a son.

MARRIAGES.

Attwater—Hawkins.—On April 29th, at St. Margaret's Church, Westminster, Harry Lawrence Attwater, M.A., M.B., M.C., F.R.C.S., Temporary Lieutenant, R.A.M.C., to Nora Collingdon Hawkins, fourth daughter of Dr. and Mrs. Hawkins, of Hillfield, Broadwey, Dorset.

Gutteridge—Baxter.—On April 23rd, at St. Giles in the Fields, London, Lieutenant Bernard George Gutteridge, R.A.M.C., to Mary, second daughter of William Baxter, Esq., of Hilston.

Milne—Brown.—On April 24th, at West Coats Parish Church, Edinburgh, Robert Milne, M.D., M.S., F.R C.S., to Alice May, second daughter of John Brown, Esq., Coltbridge-terrace, Murrayfield, Edinburgh.

Yorke—Greening.—On May 4th, at the Wesleyan Church, Frodsham, by the Rev. H. Lefroy Yorke, M.A., B.D., father of the bridegroom, assisted by the Rev. William Stevenson, Professor Warrington Yorke to Elsie, only daughter of Mr. and Mrs. N. Greening, of Newlands, Frodsham.

DEATHS.

Bell.—William Bell, M.R.C.S., J.P., V.D., son of John Bell, M.D., of Uppingham, at Rutland House, New Brighton, in his 77th year.

Blakiston.—On May 3rd, at Ashington, Glastonbury, Arthur Alexander Blakiston, M.R.C.S., aged 63 years.

Gowers.—On May 4th, at Ladbroke-square, W., Sir William Richard Gowers, M.D., F.R.S., aged 70 years.

Lawrance.—On May 1st, at his residence, Shaftesbury-road, Hammersmith, Frederick Lawrance, M.R.C.S. Eng., L.S.A., in his 85th year.

Neely.—On April 25th, killed in action at Ypres, Hugh Bertram Neely, L.D.S., Guy's Hospital, Second Lieutenant, 1st Suffolk Regiment, aged 26 years.

Simpson.—On May 3rd, at Heslington House, Worthing, Walter S. Simpson, M.R.C.S., L.R.C.P., aged 63 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

HOSPITAL ARRANGEMENTS IN THE EIGHTEENTH CENTURY.

THE excellence of the hospital arrangements in the present war has excited the admiration of all who are interested in the alleviation of the sick and wounded among those who are fighting our battles at the present time. It is a contrast to what prevailed in the end of the eighteenth century. Facts may be gleaned from a pamphlet issued by the War Office in 1796 bearing the title of "Regulations for Improving the Situation of Regimental Surgeons and Mates, and for the Better Management of the Sick in Regimental Hospitals."

Up to that date the cavalry and infantry had allowances on account of medicines and hospital expenses, and these, with any other perquisites or gratuities, were to cease, after which medicines were to be supplied by the Apothecary General, and all expenses connected with hospitals were to be defrayed at the public charge. Each surgeon was to have 12*s*. per day in the cavalry and 10*s*. in the infantry. He was to have his choice of quarters according to his standing in the regiment, and in the time of war was to have the same baggage and forage money as captains. After he had put in 20 years' service he was entitled to an allowance of 5*s*. a day for life "upon production of certificates of good conduct from the commanding officers under whom he shall have served."

Surgeons' mates were in future to be designated assistant surgeons, and their pay was to be 5*s*. per day, but if on foreign stations or during war it was increased to 7*s*. 6*d*. per day.

Every regular corps was to be furnished with an airy, roomy, regimental hospital. In the event of the regiment not being in barracks, the duty of providing a place for a hospital fell upon the regimental surgeon. During an encampment a tent was allowed in aid of, but not as a substitute for, a hospital. Great attention was to be placed as to the pitching of it, and inside straw was to be worked up into mats and laid upon dry sand or gravel under each palliasse. The sides and floors of the wards were to be washed regularly, and if any contagious disease prevailed nitrous acid was to be evaporated every day. Every man was to be allowed the space of 5 ft. for his bed and to have a bed to himself. Great care was to be shown in the passing of recruits, and at convenient times and places they were to be inoculated against small-pox.

Each regimental surgeon was to be provided with a medicine chest, calculated for a corps of 1000 men, and once a year he had to make a return to the Secretary for War of what had been used during the 12 months, the said return to be accompanied by an affidavit taken before a magistrate that none of the medicines, as far as he knew, had been converted to private purposes or applied to any use but that of the regiment. Suppose an epidemic caused a run upon a certain medicine, the extra quantity could not be supplied till the prescribed formula had been complied with. If a doctor knew of a particular medicine which in specific cases would be beneficial, if it were not in the "Dispensatory" and he desired to use it he had to procure it at his own expense. Wine was only to be given when it was indispensably necessary, and it was only to be administered to the patient by the surgeon or his assistant as medicine or with food.

Each surgeon was furnished with four sets of hospital bedding for every hundred men on home service, and with six sets, while on foreign service, the other hospital necessities being in proportion. However, he was to furnish at his own expense what instruments were required, and these were specified as "capital" and "pocket." According to the list the set of the former consisted of amputating saw, or amputating saw with spare blade, metacarpel with spare blade, 2 amputating knives, 2 tenaculums, 24 curved needles, 2 Pettit's tourniquets, 4 leather tourniquets, 6 ligatures and handle for the same, 2 linen compresses, a trephine with 4 crowns, or 2 fixed trephines, lenticular and rugine, elevator and forceps, 1 perforator, brush and key, 6 scalpels, 4 catheters, 2 probangs, 1 silver probe, 1 bullet forceps, 1 polypus forceps, 2 trocars with additional canules, or with spring canules and the additional ones, 1 trocar for the hydrocele, 1 seton needle, 1 small razor, 1 small hone, 1 syringe, 1 key instrument for teeth. 1 forceps for teeth, 1 punch for teeth, 1 strong nippers for bones, thread for ligatures. The contents of a pocket case consisted of, 1 straight scissors, 1 curved scissors, 2 silver probes, 1 steel forceps, 1 scalpel, 1 spatula, 1 straight bistoury, 1 curved bistoury, probed point, 1 gum lancet, 1 caustic case, 1 director, 12 curved needles.

Regarding the "Dispensatory," a final word of caution was given. There was to be no "useless and extravagant demands for obsolete, expensive, and inefficacious medicines," and to limit the surgeons to the use of the most approved and powerful a list was drawn up for their observance. "By this plan the prescriber sees at one view what means he has to produce the effects he wishes, no time will be lost in looking over every article of medicine in his possession, his decision will be expeditiously made, and his practice will become more rational."

The advance of medical and surgical science has enormously altered the medical care of the army, and present-day sufferers are reaping the beneficial results. But the pamphlet from which we quote shows that in the army at the end of the eighteenth century provision was made commensurate with the knowledge and experience of the time; while the comparatively small numbers of men engaged made the problems presented far less severe.

THE DEFINITION OF A CONSULTANT.

To the Editor of THE LANCET.

SIR,—In reply to your correspondent "Enquirer" in THE LANCET of May 1st, I would remark that a consultant is a professional friend, adviser, and helpmate. There is the true consultant—a *rara avis*—who sees patients only in consultation with another medical man, and there is the pseudo-consultant, who has patients of his own and is called into consultation by reason of his experience or on account of a successful reputation, sometimes to assist and advise a friend, but usually at the request of the patient or patient's friends to give a second or independent opinion.

The rules that govern the conduct of a consultant are very simple, are well recognised by every member of the profession, but are incapable of strict observance, since patients are unacquainted with the rules of professional etiquette. A doctor should not attend a patient as an independent patient whom he has seen in consultation. This rule holds good if the introduction to the patient is through the doctor, but if, on the other hand, he is sent for with a view to his taking the place of the other doctor, he is justified in accepting the patient provided he acquaints and receives the consent of the doctor in attendance. This man is going to receive his dismissal under any circumstances, and therefore the second man is not doing him any injury. A refusal to attend is misunderstood by patients. Most medical men know that certain patients constantly are changing their medical advisers. I have a patient of many years' standing, and she frequently sees two or three different doctors in the week. I have seen her at 9 A.M., another doctor has seen her at noon, and a third doctor in the afternoon. Her idea is to have the advice I may give her corroborated by independent opinion. In all these years only one doctor has written to tell me of the fact that he had been called to see her. It cannot be thought that any of these doctors believed she was without a medical adviser, as she is a chronic invalid and a great sufferer. I am, Sir, yours faithfully,

May 2nd, 1915. G. SHERMAN BIGG.

BUMBLEDOM AND HYGIENE.

IN spite of all efforts to popularise the principles of hygienic living ignorance and indifference still pervade, not only the masses, but those who are officially appointed to care for them—viz., boards of guardians. A case in point, according to a report in the *Carlisle News*, arose recently out of a complaint that two boys who were being boarded out by the Brampton board of guardians had been supplied with neither overcoats nor nightshirts. Lady Carlisle very naturally supposed that the deficiency, so far as regarded nightshirts at any rate, had only to be mentioned to be remedied; but apparently to her surprise the suggestion met with opposition on the ground that nightshirts were unnecessary, for people in the country were not in the habit of wearing nightshirts at all. Lady Carlisle, who obviously has much to learn about the mental attitude of bumbledom, insisted, with praiseworthy tenacity, on the hygienic importance of changing the sweat-soaked day clothes for fresh and aired garments on going to bed. This evoked the silly retort that the soldiers at the front did not change their shirts at night, in disregard of the fact that the soldiers at the front often have to stand for hours up to their waists in water, to go on occasion for long stretches of time without food or sleep, and to expose themselves to injuries and to many dangerous and unhealthy conditions which cannot be avoided under the circumstances, but which, if they were imposed on civilians in peace time, would evoke horror at their criminal barbarity. It was admitted in the discussion that even the inmates of the workhouse were not supplied with night clothing. The attitude of indifference received adequate expression from one of the members, who, according to the report in question, provoked laughter by the remark, "Give 'em the shirts and let us change the subject." The motion to provide nightshirts, put by Lady Carlisle, was negatived by 10 votes to 5. The importance, whenever possible, of freeing the absorbent skin at night from unnecessarily prolonged contact with the toxic products of perspiration is a well-established hygienic principle and forms an integral portion of that cleanliness which is next to godliness; and the fact that individuals under pressure of temporary necessity may not always be able to comply with it is no justification whatever of its neglect as a practice of daily life under normal conditions.

AN ATTACK OF SEVERE ILLNESS APPARENTLY DUE TO EATING RHUBARB.

To the Editor of THE LANCET.

SIR,—Five days ago I was suddenly attacked with acute sickness and diarrhœa. Pulse and temperature went up rapidly, and I felt alarmingly ill. Next day these had subsided, but I had great strangury with bloody urine, which showed a considerable deposit of albumin. The other symptoms are subsiding, but the albumin remains. I am 69 years of age, and have had no illness of any kind for many years. My bladder and renal functions have always been perfectly normal.

In trying to account for this attack the only cause I can think of is that I partook rather largely of rhubarb pudding on two occasions a few days previously. The attack was very alarming and may, of course, leave some mischief of a chronic nature behind. Can it be due to oxalic acid known to be present in rhubarb? It would be interesting to know if any of your readers have had a similar experience.

I am, Sir, yours faithfully,
M.D.

May 3rd, 1913.

SACRED RELICS AS CURATIVE AGENTS.

THE desire for relics—i.e., for memorials of those whom we love or honour or both combined—is one of the oldest of human passions, and that cures would be wrought by such relics was an instinctive belief. Perhaps the earliest instance on record of a cure wrought by relics is that mentioned in the Second Book of Kings, where in Chapter 13, v. 21, we read that a dead man was cast into the sepulchre of Elisha and revived on touching the prophet's bones. In the fourth century A.D. thousands of pilgrims went to the Holy Land and other places of the East to see the holy paces and such things as the instruments of the Passion, relics of the martyrs, Job's tomb and his dunghill. Concerning the last-named we learn from St. Chrysostom that many "took a long journey over the sea from the ends of the earth to see it and that from the sight thereof they derive every help and much 'philosophy,'" meaning probably by this last word a method of regular holy life. In the later Middle Ages the cult of relics became a scandal in many ways, witness Chaucer's description of the Pardoner with his collection of relics, such as Our Lady's veil and the glass of "pigges bones." To go back a few centuries, states and countries vied with one another as to which of them should own the more important relics, and the State of Venice in particular had a passion for relics. It began with the body of St. Mark, which was stolen or rescued from the infidels of Alexandria, in about 827, by means of a somewhat unworthy trick, and after the sack of Constantinople in 1204 she acquired, among other relics, the arm of St. George the Martyr, part of the body of St. John Baptist, and some of the Holy Blood. Later, in 1237, the Crown of Thorns, which had been in the sanctuary of Constantinople and had been mortgaged to a Venetian, was redeemed by St. Louis of France and deposited in the Sainte Chapelle. Numerous instances of cures wrought by relics are on record—for example, that performed upon a niece of Pascal, on March 24th, 1653, whose ulcer was touched and cured by a thorn from the Crown.

Some new and curious details concerning this widespread belief are furnished in a work recently published in Holland by Dr. A. Eekhof upon the Wandering Missionaries, or *Quaestuarii*, who sold indulgences, and during their peregrinations for this purpose wrought many wonderful cures by means of relics. These details are compiled from a mass of forgotten documents in the episcopal archives of Utrecht. The prophylactic virtues of greatest potency appear to have been those possessed by the relics of St. Hubert, patron saint of Utrecht Cathedral. One of these, his stole, is said to have been especially efficacious for the cure of rabies. This was only to be expected from St. Hubert's connexion with the chase. The treatment consisted in making a small incision in the skin of the victim's forehead and inserting therein a thread taken from the material of the stole. The ecclesiastics of Utrecht also claimed great success in relieving the sick by the use of relics of St. Martin of Tours which had been leased by the French clerics to their brethren at Utrecht, who found them a source of revenue. Almost equally efficacious were the relics of St. Anthony, which in 1079 were brought to Flanders by a Duke Jocellinus and placed in a monastery at Belle. Their application was most valued as a remedy for the plague and for "ignis sacer." Dr. Eekhof shows from the documents how the frauds practised by the religious in relation to alleged cures were frequently exposed, until the authorisation of such "quests" was forbidden by the Council of Trent in 1563.

COMPRESSED DRUGS IN THE GERMAN ARMY.

UP to 1897 the German military medical authorities used little packets of powders which had hitherto been supplied to their hospitals and dispensaries, but they wished to replace them by something less bulky and more readily conserved during the exigencies of war. They accordingly experimented with compressed tablets and with the necessary machinery for making them. Several different kinds of tablets were produced as a result, some satisfactory and others not quite so, some being liable to deteriorate and others to melt in hot weather, and there was also the difficulty of controlling the quality and quantity of the active ingredients in the compressed tablets. Some kinds of tablets were found too difficult to make and were purchased in the open market. A list of 18 different kinds manufactured was published in THE LANCET of March 10th, 1906, p. 703, and probably has been largely added to now. After the war is over we shall learn more of the success or failure of the treatment of the troops with the new methods and preparations, made not only by Germany but by the Allies. The diminution of bulk and weight have been the main considerations, and it will be discovered how far these factors are compatible with efficacy, convenience, economy, and durability.

RESPIRATORS.

WE have received from Messrs. Solport Brothers, of 188 and 190, Goswell-road, E.C., a model respirator which seems to be suitable for the present emergency among the troops and to fulfil the required conditions satisfactorily. The model (which has been submitted to the War Office) is called "Portia" No. 104, and is designed to be used wet, so as to cover the mouth and nose and absorb the deleterious gases. The towelling material used is specially absorbent, holding a considerable quantity of water, so that frequent renewal is not necessary, and at the same time it keeps perfectly porous so as not to impede the breathing. As a great advantage over the cotton-wool respirators it is claimed that the latter speedily become clotted into lumps after once or twice wetting and leave open patches through which the air is inhaled without proper filtration. The texture of "Portia" No. 104 respirators is said to remain uniform and constant, no matter how long the respirator is used or how frequently it is wetted.

THE PUBLIC SCHOOLS YEAR BOOK.

THE 1915 edition of this useful annual, edited by H. F. W. Deane, M.A., F.S.A., and W. A. Evans, M.A. (London: The Year Book Press. Pp. 774. Price 5*s.* net), now in its twenty-sixth year of publication, is the official work of reference to the Headmasters' Conference, and forms an admirable guide for parents and guardians seeking a suitable school for boys, giving, as it does, the names of the staff, with information as to mode of entrance, fees, prizes, scholarships, and so forth at the different public schools of the country. The sections dealing with the navy and army have been brought up to date.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

The following magazines, journals, &c., have been received:—Canadian Medical Association Journal, Therapeutic Gazette, Practitioner, Journal of Mental Science, St. Bartholomew's Hospital Journal, South African Medical Record, Annales de Gynécologie et d'Obstétrique, Journal of Dental Science, Journal of Laryngology, Rhinology, and Otology, School Hygiene, British Journal of Children's Diseases, Candid Review, Dominion Medical Monthly, Journal of Royal Sanitary Institute, Canadian Practitioner, New Zealand Medical Journal, Medical Review, Archives of Internal Medicine, British Review, Middlesex Hospital Journal, Interstate Medical Journal, &c.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—4 P.M., Election of Fellows. Papers:—Elizabeth A. Fraser and Prof. J. P. Hill: The Development of the Thymus, Epithelial Bodies and Thyroid in the Vulpine Phalanger (Trichosurus Vulpecula).—Elizabeth A. Fraser: Some Observations on the Development of the Thymus, Epithelial Bodies and Thyroid in Phascolarctos, Phascolomys, and Perameles (communicated by Prof. J. P. Hill).—Mr. J. H. Brinkworth: Measurement of the Specific Heat of Steam at Atmospheric Pressure and 104·5° C., with a Preface by Prof. H. L. Callendar (communicated by Prof. H. L. Callendar).—Mr. C. F. Jenkin and Mr. D. R. Pye: Thermal Properties of Carbonic Acid at Low Temperatures. II. (communicated by Sir A. Ewing).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

THURSDAY.

SECTION OF NEUROLOGY (Hon. Secretaries—T. Grainger Stewart, H. Campbell Thomson): at 8 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

Clinical Meeting.

Members who desire to show cases are requested to communicate as soon as possible with Dr. H. Campbell Thomson, 34, Queen Anne-street, W.

FRIDAY.

SECTION OF OTOLOGY (Hon. Secretaries—W. M. Mollison, E. D. D. Davis): at 5 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

Clinical and Pathological Meeting.

Cases and Specimens:

Will be shown by Mr. Richard Lake, Dr. Dan McKenzie, Mr. C. E. West, and Mr. W. M. Mollison.

Dr. Dan McKenzie: Note on Mastoid Grafting.

CLINICAL SECTION (Hon. Secretaries—Thomas H. Kellock, David Forsyth): at 8 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

SATURDAY.

SECTION OF BALNEOLOGY AND CLIMATOLOGY (Hon. Secretaries—Charles W. Buckley, J. Campbell McClure): at 12.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

2 P.M., Leave the Society's house for visit to Epsom College, &c.; for details see special card.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., General Meeting. Election of Officers and Council for 1915–1916 Session, &c. 8.30 P.M., Mr. D'Arcy Power: Short Demonstration on Early Books on Naval and Military Surgery from the Society's Library (illustrated by the epidiascope). Exhibition of a Selection of Some of the Society's Old and Rare Medical Works.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY.—8 P.M., Cantor Lecture:—Dr. D. Sommerville: Foodstuffs. (Lecture III.)

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common, S.W.

WEDNESDAY—9 P.M, Discussion on the Car in Medical Practice (opened by Mr. C. Ryall).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 10.30 A.M., Medical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—10 A.M., Dr. Owen: Demonstration of Cases in Wards. 12 noon, Mr. T. Gray: Demonstration of Fractures, &c. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 11 A.M., Mr. Souttar: Demonstration of Minor Operations. 12 noon, Lecture:—Mr. Souttar: Abdominal Diagnosis. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 10.30 A.M., Surgical Registrar: Demonstration of Cases in Wards. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M. Clinical Lecture.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Prof. C. S. Sherrington: The Animal Spirits. (Lecture II.)

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	1	0	One Year	£1	5	0
Six Months	0	12	6	Six Months	0	14	0
Three Months	0	[illegible]	6	Three Months	0	7	0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters &c., have been received from—

A.—Alexandra Therapeutic Institute, Lond.; Admiralty, Medical Department, Director-General of; Messrs. Arnold and Sons, Lond.

B.—Messrs. W. Baker and Co., Oxford; Messrs. Bishop, Lond.; Captain J. A. Bennett, R.A.M.C., South Farnborough; Messrs. W. Browning and Co., Lond.; Messrs. Butterworth and Co., Lond.; Messrs. Burt, Boulton, and Haywood, Lond.; Bristol Royal Infirmary, Secretary of; Messrs. Burroughs Wellcome and Co., Lond.; Messrs. W. H. Bailey and Son, Lond.; Messrs. R. and J. Beck, Lond.; Mr. G. Sherman Bigg, Lond.; Mr. F. W. Barker, Jhansi; Messrs. T. B. Browne, Lond.; Lieutenant J. Horatio Baldwin; Messrs. J. Beal and Son, Brighton; British Fire Prevention Committee, Lond., General Hon. Secretary of; Messrs. J. Bibby and Sons, Liverpool; Bootle, School Medical Officer of.

C.—Dr. B. G. Chatterjee, Kandi; Surgeon G. Cochrane, R.N., Lond.; Cafolin Co., Lond.; Messrs. R. Carruthers and Sons, Inverness; Mrs. Craven, Southport; Canterbury Mental Hospital, Clerk to the; Mr. Howard V. Cox, Lond.; Sir W. Watson Cheyne, Bart., Chatham; Dr. H. P. Cholmeley, Forest Row; Dr. E. M. Clarke, Truro; Dr. Herbert E. Cuff, Lond.; Dr. A. K. Chalmers, Glasgow; Mr. W. E. Crowther, Howden; Dr. A. Charpentier, Uxbridge; Messrs. J. and A. Churchill, Lond.; Major Caie, R.A.M.C., Norwich; Cheshire County Asylum, Macclesfield, Clerk to the.

D.—Messrs. W. Dawson and Sons, Lond.; Lord Derby War Hospital, Warrington, Clerk to the; *Devon and Exeter Daily Gazette*, Manager of; Messrs. J. Dickinson and Co., Hemel Hempstead; Derbyshire County Council, Derby, Accountant to the; Derby Amalgamated Friendly Societies' Medical Association, Secretary of; Mr. T. N. Darling, France; Messrs. Dunville and Co., Lond.; Mr. R. Davis, Lond.; Mr. Percy Dunn, Lond.; Mr. J. Dawson, Lond.; Mr. H. Dickinson, Lond.; Mr. John Dover, Totland Bay; Mr. R. H. Dickson, Newcastle; Dowsing Radiant Heat Co., Lond.

E.—Mr. J. Howell Evans, Lond.; Messrs. W. Edwards and Son, Lond.; Dr. N. Erian, Cairo; Emergency; Dr. C. T. Ewart, Woodford Bridge.

F.—Dr. Leonard Findlay, Glasgow; Dr. J. M. Fortescue-Brickdale, Clifton; Fine Art Society, Lond.; Factories, Chief Inspector of, Lond.; Mr. W. D. Fowell, Lond.; Colonel F. E. Ford, France.

G.—General Life Assurance Co., Lond., Secretary of; Mr. H. Giles, Norwich; Glasgow Corporation, Chamberlain to the; Mr. Charles Gibbs, Lond.; Mr. L. Guggenheim, Lond.; Mr. H. J. Gauvain, Alton; Messrs. Robert Gibson and Sons, Glasgow; Mr. A. Graham, Lond.

H.—Holborn Surgical Instrument Co., Lond.; Hampshire County Medical Officer of, Winchester; Hove, Medical Officer of Health of; Dr. Hill, Jarrow; Messrs. Hough, Hoseason, and Co., Manchester; Mr. C. H. Holdsworth, Lond.; Mr. Francis Heatherley, Rock Ferry; Lieutenant J. B. Haycroft; Lieutenant Arthur Hare, R.A.M.C.; Mr. Paul B. Hoeber, New York; Dr. Walter Haward, Lond.; Messrs. C. J. Hewlett and Son, Lond.; Dr. Heilborn, Bradford; H. S. R.

I.—International News Co., Lond.; Imperial Institute, Lond., Director of.

J.—Dr. F. Wood Jones, Lond.; Mr. W. Jacob, Lond.

K.—King Edward VII. Sanatorium, Lond., Secretary of; Mr. Edmond Knight, Lond.; Mr. Christopher Kempster, Lond.

L.—Mr. H. K. Lewis, Lond.; Dr. R. Cranston Low, Edinburgh; Captain T. Lyon, Shorncliffe; Messrs. E. and S. Livingstone, Edinburgh; London Dermatological Society, Hon. Secretary of; Dr. R. Bruce Low, Lond.; Local Government Board, Lond.; Dr. C. E. Lea, Manchester; Dr. F. Langmead, Lond.; Messrs. Lee and Nightingale, Liverpool; Mr. John Lomax, Lond.

M.—Messrs. Mather and Crowther, Lond.; Manchester Northern Hospital, Secretary of; Metropolitan Ear, Nose, and Throat Hospital, Secretary of; Captain W. L. Maclean, France; Dr. J. G. Gordon Munn, Norwich; Monmouth County Asylum, Abergavenny, Clerk to the; *Midland Counties Herald*, Birmingham, Manager of; Medical Society of London, Registrar of; Dr. J. C. McWalter, Dublin; Dr. E. D. Macnamara, Lond.; Medico-Psychological Association of Great Britain and Ireland, Lond.; Mr. F. C. Madden, Cairo; Manhu Food Co., Liverpool; Mr. R. M. Morrison, Lond.; Mellin's Pharmacy, Lond.

N.—Nottingham Children's Hospital, Secretary of; Newcastle-upon-Tyne Corporation, Accountant to the; North Ormesby Hospital, Middlesbrough, Secretary of; Messrs. R. Neill and Sons, Bangor; North Wales Counties Asylum, Denbigh, Steward of.

O.—Sir William Osler, Bart., Oxford; Dr. K. Omata, Swatow.

P.—Dr. L. H. Pegler, Lond.; Perrier, Ltd., Lond.; Lieutenant H. S. Pemberton, R.A.M.C.; Mr. M. Palmer, Guayaquil, Prestwich County Asylum, Manchester, Clerk to the; Mr. H. M. Page, Lond; Mr. W. H. Plows, Lond.; Dr. Eric Pritchard, Lond.; Lieutenant J. Picton, R.A.M.C.

Q.—Queensland Government Statistician, Brisbane.

R.—Mr. R. Ram, Glasgow; R. S.; Radcliffe Infirmary, Oxford, Secretary of; Lieutenant D. O. Riddel, R.A.M.C., Maidstone; Rotherham Hospital, Secretary of; Royal Surrey County Hospital, Guildford, Secretary of; Mr. Paul Bernard Roth, Lond.; Registrar-General, Lond.; Royal Academy of Medicine in Ireland, Dublin; Royal Society, Lond.; Royal Sanitary Institute, Lond.; Dr. Robert R. Rentoul, Liverpool: Mrs. Aubrey Richardson, Lond.; Royal Society of Arts, Lond.; Royal Institution of Great Britain, Lond.

S.—Mr. J. D. Staple, Bristol; Messrs. Sperling and Kupfer; Milan; Professor W. Stirling, Manchester; Sheffield Corporation, Medical Officer of Health to the; Professor Sahli, Bern; Mr. F. W. Sears, Lond.; Surgeon G. J. C. Smyth, R.N., Lond.; Messrs. Sewell and Crowther, Lond.; Messrs. W. H. Smith and Son, Folkestone; Smith's Advertising Agency, Lond.; Sheffield Royal Hospital, Secretary of; Dr. G. M. Sydenham, Uckfield; Mr. D. H. Shuttleworth-Brown, Wimbledon; St. Marylebone War Hospital Supply Depot, Lond., Committee of; Major E. M. Sympson, R.A.M.C.; Sir G. H. Savage, Lond.; Mr. C. St. Aubyn-Farrer, Lond.; Scholastic, Clerical, and Medical Association, Lond.; Scotswomen's Publishing Society, Edinburgh; Messrs. G. Street and Co., Lond.; Messrs. Solport Bros., Lond.

T.—Mr. Sydney Tibbles, Lond.; Messrs. C. Tuckey and Co., Lond.; Dr. John Tatham, Old Oxtead; Dr. J. C. Thresh, Chelmsford; Mr. G. L. Travis, Llandudno; Tunbridge Wells General Hospital, Secretary of; Dr. Barbara Tchaykovsky, Harrow-on-the-Hill; Lieutenant E. Taunton, R.A.M.C.; Dr. A. Turner, Plympton.

V.—Messrs. J. W. Vickers and Co., Lond.; Verkehrsverein, Davos; Mr. Dennis Vinrace, Lond.; Dr. Walter Verdon, Lond.

W.—Worcester County and City Asylum, Clerk to the; Messrs. J. Wright and Sons, Bristol; Mr. T. R. Watson, Nordrach-on-Dee, Banchory; Mr. G. Watson, Ipswich; Mr. S. S. M. Wood, Lond.; Mr. C. M. Webb, Rangoon; West London Medico-Chirurgical Society, Hon. Secretary of; Dr. S. A. K. Wilson, Lond.; West London Hospital Post-Graduate College; Mr. Charles Wray, Lond.; Mrs. Witt, Salisbury; West Bromwich and District Hospital, Secretary of; Whitechapel Dispensary for the Prevention of Consumption, Lond., Secretary of; Messrs. J. Williams and Son, Bradford; Wounded Allies Relief Committee, Lond.; Mr. C. Hamilton Whiteford, Plymouth; Mr. G. Bennett Waters, Lond.

Y.—Dr. E. McKillop Young, Hulan Fu; Dr. A. M. F. de Ybarra, Havana.

Letters, each with enclosure, are also acknowledged from—

A.—Messrs. Allen and Hanburys, Lond.; A. C.; Ancoats Hospital, Manchester, Secretary of; Messrs. Adlard and Son, Lond.; Mr. J. Anderson, Glasgow; A. G. R. H.

B.—Mr. J. J. Barry, Fermoy; Mr. A. S. Blundell Bankart, Lond.; Mr. H. Butterfield, Northampton; Mr. H. Blakeway, Lond.; Burnley Guardians, Clerk to the; Birkenhead and Wirral Children's Hospital, Secretary of; Blackburn Guardians, Clerk to the; Bristol Eye Hospital, Secretary of; British Oxygen Co., Lond.; Dr. W. B. Bell, Liverpool; Mr. A. B. Barrow, Lond.; Mr. E. Blatchley, Lond.; Mrs. Behnke, Lond.; Mr. P. A. Bernard, New York; Mr. J. Bray, St. Leonards-on-Sea.

C.—Dr. C. W. Cunnington, Lond.; Dr. J. H. Collier, Bettws-y-Coed; Cumberland Infirmary, Carlisle, Secretary of; Dr. E. W. Carmichael, Edinburgh; Cheltenham General Hospital, Secretary of; Messrs. J. and A. Carter, Lond.; Mr. A. R. Carver, Llanstephan; Dr. S. R. Collier, Wimbledon; Corn Products Co., Lond.; Chester Corporation, Treasurer to the; Dr. G. P. Campbell, Falmouth, Jamaica.

D.—Mr. F. H. Duke, Hoopstad; Delhi and London Bank, Calcutta, Manager of; Dundee Royal Infirmary, Treasurer to the; Mr. A. H. P. Dawnay, Lond.; Dorland Agency, Lond.

E.—East London Hospital Board, South Africa, Secretary of; Surgeon T. Leslie Ellis, R.N.V.R., Lond.

G.—Gloucestershire Royal Infirmary, Gloucester, Secretary of; Galen Manufacturing Co., Lond.; Messrs. Gale and Co., Lond.; Glenn Co., Garwick; Dr. S. Gill, Formby.

H.—Mr. W. K. Heffernan, Thurles; Messrs. J. Haddon and Co., Lond.; Miss J. Hastie, Lond.; Sir Victor Horsley, Lond.; H. S.; Dr. W. N. Head, Parkstone; Mr. W. S. Handley, Lond.; Hulme Dispensary, Manchester, Secretary of; Mr. C. H. Harding, Whittlesea.

I.—Ingress Abbey Military Hospital, Greenhithe; Invalid Transport Corps, Lond.

J.—Mr. T. R. Judson, Reigate; J. G. M.; Mr. J. F. Jennings, Lond.

K.—Miss A. D. Kerr, Gisborne; Kensington Tuberculosis Dispensary, Lond., Secretary of; Kreochyle Co., Lond.; Kent and Canterbury Hospital, Secretary of; Mr. G. Kaufmann, Lond.

L.—Messrs. Leslies, Lond.; Dr. E. G. Little, Lond.; Leicester Royal Infirmary, Secretary of; Liverpool Royal Infirmary, Secretary of; Mr. J. E. Lane, Lond.; Locum, Steeple Claydon; Dr. L.; Lochgoilhead and Kilmorich Parish Council, Clerk to the; Messrs. Leathwaite and Simmons, Lond.

M.—Dr. T. D. Moffatt, Ardgay; Maltine Manufacturing Co., Lond.; Medicus, Manchester; Mr. J. B. Macalpine, Manchester; Dr. L. P. Mulligan Phibsborough; Messrs. Meister; Lucius, and Brüning, Lond.; Messrs. Miller, Son, and Co., Lond.; Messrs. J. Menzies and Co., Edinburgh; Mr. A. H. Miller, Manchester; Mr. G. A. Macleod, Oban; Mr. W. MacLellan, Lond.; Mr. J. E. May, Lond.; Dr. A. Mills, Dundee; Dr. S. J. Maher, New Haven, U.S.A.

N.—National Bank of Egypt, Cairo, Manager of; Nottinghamshire Education Committee, Nottingham, Accountant to the; Mr. J. S. Nolan, Bedwas; North Riding Education Committee, Northallerton, Clerk to the; Norwich Education Committee, Accountant to the.

O.—Mr. H. H. O'Farrell, Kew Gardens.

P.—Dr. H. Porter, Bradford; Mr. F. H. Pickin, Lond.; Messrs. W. Porteous and Co., Glasgow; Mr. J. H. Parsons, Lond.; Paisley Corporation, Chamberlain to the; Dr. W. P. Pankridge, Petersfield; Dr. C. D. Pye-Smith, Crookham; Dr. W. T. G. Pugh, Carshalton; Messrs. G. Pulman and Sons, Lond.

R.—Mr. A. T. Richardson-Jones, Abergele; Dr. A. Ross, Lond.; Royal Institute of Public Health, Lond., Secretary of; Radium Institute, Lond., Secretary of; Dr. Ruxton, Lond.; Royal Albert Institute, Lancaster, Secretary of; Royal Albert Hospital, Devonport, Secretary of; Dr. R. Rees, Southport; Mr. R. R. Ross, Rio Tinto; Mr. H. J. Roper, Leeds; Royal South Hants and Southampton Hospital, Secretary of; Dr. M. Read, Worcester; Messrs. Robinson and Sons, Lond.

S.—W. B. Saunders Co., Lond., Dr. J. A. Shaw-Mackenzie, Lond.; St. Andrew's Hospital, Northampton, Clerk to the; Salford Corporation, Treasurer to the; Stretton House, Church Stretton, Medical Superintendent of; Messrs. Saward, Baker, and Co., Lond.; Dr. S.; Messrs. T. G. Scott and Son, Lond.; Messrs. W. H. Smith and Son, York; Messrs. Spiers and Pond, Lond.; Messrs. W. H. Smith and Son, Lond.

Waddelow, Whittlesea; Wakefield Corporation, Accountant to the.

Y.—York County Hospital, Secretary of.

The Hunterian Lecture

ON

SOME INFECTIONS OF THE TONSILS.

Delivered before the Royal College of Surgeons of England on Feb. 19th, 1915,

BY FREDERICK C. PYBUS, M.B., M.S. DURH., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON TO THE HOSPITAL FOR SICK CHILDREN, AND SURGICAL REGISTRAR TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—My first duty is to thank you for the honour you have done me by appointing me one of your Hunterian professors during the present year.

INTRODUCTION.

In selecting a subject for this lecture I was guided mainly by the fact that for some time I have been studying the pathology of the tonsils, and also because most questions relating to them have been for some time past under discussion. Some problems have been satisfactorily dealt with, others are in the process of elucidation, while there remain more which need much further investigation before definite opinions can be stated about them or any conformity of views reached. It seemed to me wise at the same time to review, as far as possible, the subject of tonsil infections. While some authorities consider that the tonsil is ruthlessly and unnecessarily sacrificed, others are tardy in recognising the part played by that organ as a focus of infection, and perhaps err in the opposite direction. I hope to be able to give some guidance in this matter, and quote the principles and results of my own practice.

ANATOMY.

The faucial tonsil which lies between the pillars of the fauces is the most complex part of the lymphoid tissue situated at the entrance of the alimentary canal. In structure it resembles a lymphatic gland, and is surrounded for the most part by a tough fibrous capsule, which is connected to the structures forming the pharynx by loose areolar tissue, except at its lower pole, where it receives its main vessels and has some muscular attachments. This capsule allows the tonsil to move on the pharyngeal wall and is a potent protection against the spread of infection. The remaining surface of the tonsil is exposed in the pharynx, its extent varying greatly in degree. From this pharyngeal aspect a pocket projects into the tonsil, which is in reality a hollow organ, this cavity being intracapsular and known as the tonsillar fossa. The pharyngeal aspect of the tonsil is covered by the same epithelium as the general surface, and is thrown into folds which surround numerous depressions or lacunæ; these extend through the lymphoid tissue, so that their blind extremities abut on the capsule. Certain folds of mucous membrane pass from the faucial pillars to the surface of the tonsil and may very considerably narrow the entrance to the tonsillar fossa. As the lymphoid tissue grows on the sides and folds, the fossa may be largely obliterated, and later the tonsil appears almost solid. In its commonest form the tonsil consists of an almost solid lower pole—containing narrow lacunæ, while the fossa lies above the level of the soft palate and is bounded by folds of lymphoid tissue. More or less of the tonsil may project beyond the inner border of the faucial pillars. As the tonsil enlarges it tends to project inwards, but it may remain entirely behind the anterior faucial pillar, and I estimated from an examination of 500 tonsils that only in 15 per cent. of cases did more project than remain hidden.

The main efferent lymphatic vessels pass from the tonsil to a gland belonging to the deep cervical chain, and situated below and behind the angle of the jaw in the interval between the internal jugular and common facial veins. Afferent lymphatics have not been demonstrated, but experiments by Lénárt, Henke, and others have shown that pigment injected into the nasal mucous membrane may be found after a short interval in the substance of the tonsil, and they suggest that such afferent lymphatics do exist.

The comparative anatomy of the tonsil investigated by Hett in this country, and whose specimens are present in the Museum, demonstrates that in successive grades of animals the tonsil increases in complexity from a mere depression lined by lymphoid tissue to the complicated arrangement found in the higher species. The lacunæ, at first solid columns of epithelium, break down and form cavities which remain throughout life. As we should expect, the tonsils most nearly corresponding to the human are those of the monkeys and anthropoid apes.

PHYSIOLOGY.

The tonsil, as already stated, forms part of the ring of lymphoid tissue which guards the entrance to the respiratory and digestive tracts. The exact nature of its function is difficult to determine, as extirpation of the organ, so far as can be discovered, causes no defect in the economy. No doubt its function can still be carried on by the remaining lymphoid tissue in the vicinity. As with adenoid tissue elsewhere it reaches its maximum growth in childhood and gradually atrophies as adult life is reached. The maximum activity is correlated to that time of life when infection is most frequent, as with the remainder of the lymphoid tissue, situated along the whole course of the alimentary canal. An examination of the tonsil shows it to have a similar structure to a lymphatic gland, and as such it is actively engaged in the production of lymphocytes. It may receive lymph from the nasal cavities and act as a filter and protecting agent in infections in this region. It has been shown that pigment granules injected into the nasal mucous membrane find their way into the tonsil and in some cases may be extruded from here on to the free surface. The lymphocytes also are constantly reaching the surface, where they mingle with the oral secretions. An examination of the contents of the lacunæ shows them to be occupied by lymphocytes, leucocytes, and organisms. Many of the latter are ingested and destroyed in the lacunæ, while in some cases they find their way through the epithelium—again to be received, in normal conditions, by leucocytes, where they are satisfactorily accounted for. This process may be studied by the application of carmine granules to the surface of the tonsils. There thus appears to be a constant stream of cells wandering to the surface of the tonsil and finding their way into the lacunæ and oral cavity, in which places they may act as phagocytes, not only to foreign particles but to organisms as well. There is no doubt that their function is protective and the tonsils enlarges temporarily beyond normal limits to deal with increased infection. In addition to this active defence, the lacunæ occupied by organisms of various nature, pathogenic and others, act as culture tubes, and it seems probable that under strictly normal conditions the epithelium is a sufficient protection against the entrance of organisms into the tonsillar tissue, but the balance is so delicate that it is frequently found that organisms do pass into the substance of the tonsil, where in the great majority of cases they are destroyed, and by this process of absorption of organisms or toxins the tonsils may act as immunising agents to the body as a whole.

There are some who ascribe some particular internal secretion to the tonsil, but the evidence for this is by no means conclusive. In summing up we may state that the tonsils may act as lymphatic glands for certain regions of the nasal cavities. They act also as a protection against the constant presence of organisms in this part of the pharynx—either in the mouth, lacunæ, or tonsil substance—should they reach it through some breach in the surface. It is also probable that in the exercise of this phagocytosis they confer some immunity against the organisms inhabiting this region.

BACTERIOLOGY.

The tonsils are subject to the presence of organisms during almost the whole of life, both on their surface and in the lacunæ which penetrate their substance. Under normal conditions no active invasion is apparent, but under the influence of local injury or lowered resistance infection takes place with effects of very varying magnitude.

The regular inhabitants of the mouth and throat may be found on cultural examination of the contents of the lacunæ. They vary in proportion at different times, and on occasions rarer pathogenic forms can be found or show their presence by causing some lesion. Dwyer, in an examination of 72 cases, found the following organisms present in health, the varieties ranging from 1 to 7 (Table I.).

TABLE I.—*Bacteriology of the Tonsils* (*Dwyer*).

	Cases.		Cases.
Streptococcus (various types)	50	Diplococcus mucosus capsulatus	4
Pneumococcus	14	Influenza bacillus	5
Staphylococcus	20	Pyocyaneus	1
Micrococcus catarrhalis	12	Friedländer's bacillus	1
Diphtheria bacillus (5 true type, 5 pseudo, 5 not determined.)	16	Spirillum	1
		Long curved bacillus	1

In pathological conditions the normal balance of varieties may be upset, while additional organisms may be present, such as (1) the bacillus of tuberculosis; (2) actinomycosis; and (3) bacillus coli. The most constant organism present, as is well known, is the streptococcus, and it can be found in nearly 100 per cent. of examinations. All the organisms above mentioned are capable of producing infection of the tonsil, though some may exist in contiguity with it throughout a lifetime and produce no harmful effect.

Active invasion of the tonsil may occur through the lymphatic channels leading from an infective condition of the nose. More often, however, the infection is from the surface and is determined occasionally by injury, but more often without any gross mechanical factor, it being dependent on an increased virulence of the organism or some lessening of the chemical defences of the body. The organisms are contained at the time in the secretions of the mouth or may be carried to the tonsil in food, such as will be shown to occur with the tubercle bacillus, or by air, especially in mouth-breathers. The organisms in the food may be forced directly into the lacunæ or may be carried in on some foreign particles, such as a fig-seed, which I have found on at least two occasions.

The lesion may be limited to the surface of the organ and be associated with a catarrhal condition of the rest of the pharynx. The invasion may then spread to various depths and become subepithelial, lacunar, or in the substance of the tonsil. From the tonsil spread is limited largely by the capsule, but infection may take place through this, either by means of the lymphatics or through some aperture, and so invade the cellular tissue, causing peritonsillar infection. Further spread passes to the lymphatic glands, and from here to the circulation, and may become widespread.

All forms of inflammation may subside completely and leave little trace of their presence. Fibrosis or suppuration may result in each situation. In some cases, as in other parts of the body, infection may not be entirely overcome and may show itself at irregular intervals during the whole life of a person, or the infection may become encapsulated, as in some of the tonsils exhibited.

The effect of organisms on the tonsil varies considerably, depending on the nature of the organism and length of time that infection has been occurring. It may have a stimulating influence and cause hypertrophy, this overgrowth being of such a nature that it subsides when the infection is overcome or removed. This enlargement may be followed by atrophy or the infected tonsil from the first may not enlarge; indeed, the smallest tonsil may be grossly pathological, and such disease may be entirely hidden from view, and can be judged only by its results on the lymphatic glands or rest of the body.

INFECTION.

Passing to consider some individual infections and their special manifestations, I need only mention that occasionally the tonsil is the focus of infection in syphilis and may be the seat of a primary chancre. It has been estimated that 10 per cent. of all extragenital chancres make their appearance on the tonsil.

ACTINOMYCOSIS.

The streptothrix group of organisms may gain access to the throat and in rare cases settle in the tonsils to such an extent as to form a recognisable lesion. This consists in the production of a granuloma which may ulcerate and infect the neighbouring tissues. This tendency to spread locally causes the tonsil also to be involved secondarily in the pharyngeal and buccal forms of the disease. When an extensive lesion is present it is impossible accurately to determine the exact point of origin.

Ruhrah, in an analysis of 632 cases, found that the head and neck were involved in 57 per cent. of the cases. Of 109 cases occurring in the United Kingdom during the years 1884–1906, the face and neck were involved in 50, and of these 2 were situated in the tonsil. In a systematic examination of 75 tonsils removed for hypertrophy and examined by Wright, one case of actinomycotic infection was found, the patient being a boy aged 12 years. Similar cases have been recorded by Ruge and Lesin, the former mentioning four cases, the latter one.

The organism gains entrance in the food-supply and may lodge in carious teeth, in the tonsils, or other parts of the mouth. It may be conveyed directly in grain, and two cases are reported where the husk of grain was known to have lodged in the tonsil a short time before the symptoms presented themselves. Johne also reports a case where he found a barley husk in the actinomycotic tonsil of a pig.

A more frequent source of origin must be looked for, however, as in other examples of actinomycosis, for a history of the ingestion of raw grain cannot always be obtained. Recent investigations have shown that the organism responsible for the disease occurs in milk, and it has been demonstrated that some cows considered clinically to be suffering from tuberculous udders were found on more careful examination to be affected with actinomycosis. Further researches are being carried out on this question.

The disease commences by a swelling which may be mistaken for an inflammation or sarcoma. Later ulceration occurs, with the discharge of pus containing the characteristic granules on which the diagnosis depends.

TUBERCULOSIS.

The tonsil is frequently the seat of tuberculosis; its situation is such that any bacilli entering the mouth and being swallowed pass over its surface and may gain entrance to the crypts, whether dust-borne in the air or in the food. The unfiltered air in mouth-breathers reaches this part directly, and the presence of tubercle bacilli in dust has been abundantly proved. An examination of sputa found on the ground was recently undertaken, and it was found that tubercle bacilli were present in 60 per cent. Of the food milk is probably the most important vehicle. Recent examination of the milk-supply of Edinburgh by Mitchell has shown that in 406 samples of milk from 406 shops tubercle bacilli were found in 82, or 20 per cent. The tonsil as the first part of the lymph system of the alimentary canal is frequently involved, but the remainder of the intestinal submucous lymph collections do not escape, and both lead to involvement of the neighbouring lymphatic glands.

The following table (Table II.) of results obtained by Dr. Stanley Griffith shows that the conditions can be produced experimentally. Feeding with tubercle bacilli infects the tonsil, and from here the cervical glands; in a similar way the same conditions are produced lower down—namely, infection of the lymphoid tissue of the intestine and mesenteric glands. This fact emphasises the importance of considering tuberculosis a generalised disease, and that if the tonsil is involved it is probable that there are similar and more extensive lesions in the alimentary canal.

* A tenth had a tuberculous ulcer on the pharyngeal wall with normal tonsils.

Frequency of Tuberculosis of the Tonsil.

The frequency of tuberculosis of the tonsil has been variously estimated. Amongst tonsils removed for hypertrophy and examined for this disease, the percentage varies about from 3 or 4 to 6, and Table III. gives the figures arrived at by different investigators. This percentage is probably too low, for in the first place the tonsil in this disease is often small, and the most reliable observations must be by a combination of methods, histological, cultural, and by inoculation. In grosser infections where the lung is involved, and in those dying from phthisis or from tuberculosis in other situations, the tonsil is much more often involved. The post-mortem record of those dying from phthisis shows that tuberculous infection is present in at least 90 per cent. of the cases (Table IV.). In tuberculosis of the cervical glands the tonsils can be found to be tuberculous in at least 30 per cent. of the cases (Table V.).

Tuberculous Lesions of Tonsils and Cervical Glands.

When settled in the tonsil the tubercle bacilli produce their characteristic lesion—the miliary tubercle—which may undergo fibrosis or caseation. The tubercles may be situated near the mouth of the lacunæ, round their circumference, or in the depths of the tonsil close to the capsule. The size of the infected organ varies considerably, most often it is enlarged and fleshy, in other cases small and shrunken. Unfortunately, there are no characteristic signs. The enlarged tonsil may be firm or unduly friable, or its substance may appear yellowish. In other cases it may contain a mass of caseous débris occupying a ragged cavity in the interior or a small chronic abscess surrounded by a firm capsule of fibrous tissue. The small tonsil may be fibrous and also contain a chronic abscess. Ulceration is rare; I have not yet seen a case in the child, but in the adult this sometimes occurs, usually late in the progress of the disease. Even when extensively diseased the capsule remains free and the tonsil can be readily dissected from its bed.

It is almost impossible to recognise the tuberculous tonsil clinically—its nature can only be suspected before removal, and on gross section after removal there is often considerable doubt. Its presence can be determined clinically, only by its effects—namely, infection of the cervical lymphatic glands. This lesion is undoubtedly the main importance of the tuberculous tonsil. In children affected with this condition, analysis shows that in 70 per cent. of the cases the tonsillar gland is involved, either alone or being the largest of a set occupying the side of the neck. From this gland the infection spreads to others situated around it, and may eventually involve the whole deep cervical chain. In rare cases the tonsillar gland overcomes the infection, while glands lower in the chain may caseate and form an abscess.

Unfortunately the tuberculous tonsil rarely causes symptoms apart from glandular infection. There is no pain, attacks of inflammation are rare, and appearances are normal. It is this which has so often led to the focus of infection in tuberculous cervical glands being overlooked. In some cases the glands become apparent and enlarged after a sore-throat, but even in these cases no secondary infection can be found in the gland. The tendency of the disease is towards natural cure, and the infection of both tonsil and glands may remain latent till adult or middle life is reached, when a tuberculous abscess appears insidiously in the region of the tonsillar gland. On evacuation of the abscess a small caseous or calcareous gland is found lying under the deep fascia which communicates with the abscess through a narrow opening.

Bovine and Human Infection: Preventive Measures.

The largest number of figures dealing with this infection of the cervical glands are those of Mitchell, whose results coincide with my own and whose figures I quote. In an investigation of the bacteriology of 72 cases of tuberculous glands from children in Edinburgh Mitchell found that the bacillus was of the bovine type in 90 per cent. and of human type in the remaining 10. The main tonsillar gland was involved in 50 cases of the above series, with secondary involvement of the surrounding glands in most cases. The tonsils in 64 cases were investigated, 24 of which showed histological tuberculosis. In experimental inoculation 19, or 30 per cent., of these gave a positive result, of which it was determined that bovine bacilli were present in 12 and human in three. Investigations in other parts give slightly different percentages, but the matter is being investigated at present in different localities for comparison with these results.

We have thus seen that the tonsil is readily infected with either form of tubercle bacilli, investigations showing that the bovine type is most frequently present in children (Table VI.).

Although primary tuberculosis of the tonsil is not uncommon, it is unlikely to be the only lesion present. This infection of the tonsil has to be detected largely by its secondary effects on the lymphatic glands, as locally it rarely gives rise to symptoms. The treatment can be readily suggested from the previously mentioned facts. To prevent individual infection with the bovine bacillus at the present time it is essential that all cows' milk should be sterilised or should be obtained from healthy cows, those tested and found to be free from tuberculosis. The development of social legislation enforcing a pure milk-supply, which is urgently needed and which is gradually being met, will obviate the necessity for boiling milk. The potency of this mode of infection can be realised by the experiments of Delépine, who has found that one part of milk is capable of infecting 100,000 parts in sufficient degree to produce tuberculosis in guinea-pigs, so that it may be argued that the milk from a single cow with a tuberculous udder is capable of infecting the milk from a whole herd.

The preventive measures against human infection are being gradually adopted at present—namely, by isolating as far as possible the advanced cases of phthisis and the education of these people in the proper care of their sputum. When the lesion is suspected or manifest in the individual the treatment is to remove the tonsils entire in their capsule. The usual indication for this is tuberculosis of the tonsillar cervical glands. The tonsil as the focus should be removed as early as possible, except where softening or abscess formation in the glands demands that they should be dealt with first.

(*To be concluded.*)

SOMERSET INSURANCE COMMITTEE.—At the last meeting of the Somerset County Insurance Committee it was reported that 31 medical men in the county were on active service, and of these 26 were "on the panel." The chairman (Mr. J. C. Morland) stated it was quite probable that more medical men would be called away, and there might be difficulty in getting the usual prompt attention in some districts, but under the circumstances he was sure that insured persons would give every consideration for these difficulties, and he was also certain that they could rely upon the doctors left in the county to do their utmost to carry on as full and efficient a medical service as possible.

A CASE OF

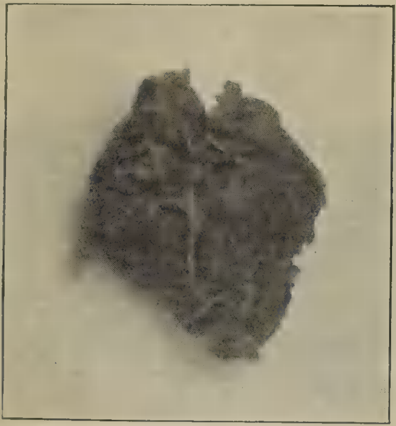
PERITHELIOMA OF THE SUPERIOR MAXILLA AND ETHMOID.

BY G. H. LAWSON WHALE, M.D. CANTAB., F.R.C.S. ENG.,
SURGEON FOR DISEASES OF THE THROAT, NOSE, AND EAR TO THE HAMPSTEAD GENERAL HOSPITAL, AND TO THE LONDON TEMPERANCE HOSPITAL.

THE patient, a female Belgian refugee, aged 52 years, came to the Hampstead General Hospital in September, 1914, with a lump in the right cheek of three and a half years' duration. The whole right upper jaw bulged outwards, pushing the nose over towards the left. There was no depression of the palate; the temporal fossa and post-nasal space were free. The right eye was proptosed, but vision was perfect; the outer wall of the right nasal fossa was pushed inwards against the septum. Examination by transillumination and puncture revealed a solid tumour. There were no palpable glands.

Under chloroform I incised the friable outer antral wall beneath the cheek, my intention being to remove a piece for histological diagnosis. But the bulk of the tumour came away so easily that I removed all I could, a mass larger than a golf-ball. (Fig. 1.) It was, however, impossible by this route to get any instrument or finger beyond the upper pole of the tumour, so it was obvious that, for a cure, this proceeding had been unsurgical and insufficient. An extract from the pathologist's report says:—

FIG. 1.

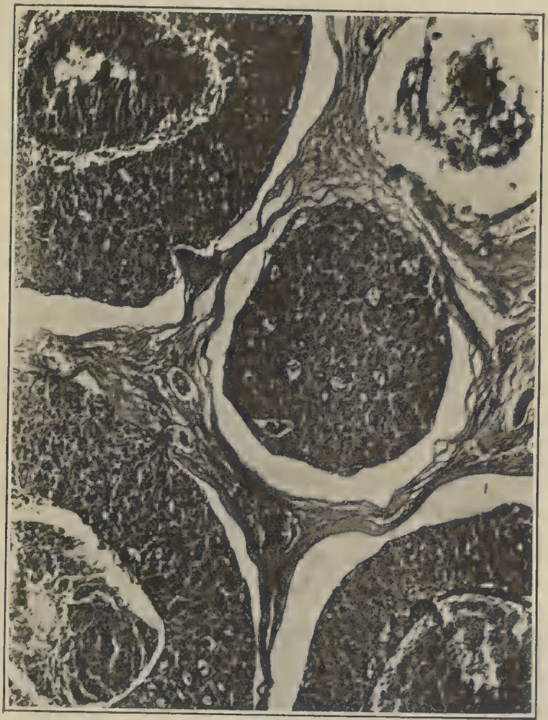


The mass of growth which was removed by elevating the cheek at the first exploratory operation. About two-thirds actual size.

> Richly cellular, irregularly circular areas present internally a roughly circular space filled with blood corpuscles. Bounding the space externally, and the cellular area internally, is a layer of flattened cells, suggesting the internal lining epithelium of a vessel. External to this are many closely packed ovoid cells, with a well-defined nucleus, arranged concentrically around the lumen. These appearances suggest a perithelioma originating in the small blood-vessels. (Fig. 2.)

A week after exploring the antrum I went to France, and so lost sight of the patient; on my return in January, 1915, I again saw her. The mass had not recurred in the outer antral wall, from where I had formerly removed the large piece, but the palate was slightly depressed on that side; the eye more proptosed and pushed outwards; the nose further displaced to the left; and a large, irregular, hard prominence extended from the middle of the cheek, upwards and inwards, crossing the inner canthus to reach the nasion. (Fig. 3.) A skiagram taken by Mr. C. Thatcher shows that the lower part of the antrum and the frontal sinuses were apparently free, but a shadow occupied the upper part of the jaw, side of the nose, and ethmoid region.

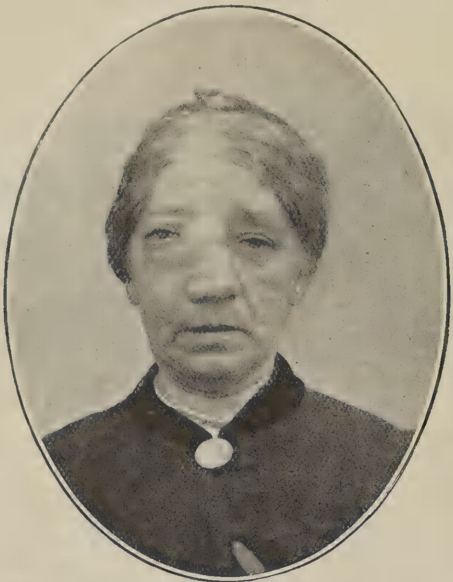
FIG. 2.



Microphotograph showing section of perithelioma of the right antrum and superior maxilla. Magnification 200 diameters.

Operation.—Ten days after the extraction of all the teeth, except those in the affected upper jaw, intratracheal ether was given by Mr. C. H. C. Visick. Dr. J. Z. Truter assisted. No preliminary tracheotomy or laryngotomy was performed, but the right external carotid was tied. An incision was then made, beginning in the middle of the eyebrow, in the line of which it was continued mesially to the root of the nose; then downwards in front of the lacrymal sac, and back to the sulcus between the nose and cheek; from here down to the junction of the nostril and cheek, horizontally inwards to the columella, and vertically downwards, dividing the lip in the mid-line. From a point in the first incision just below the lacrymal sac another curved horizontal incision was made in the line of the bony infra-orbital margin on to the malar prominence. These incisions are simply the classical one of Fergusson plus a prolongation half-way along the eyebrow. The usual large flap could now be turned down to expose the maxilla; and the skin over the root of the nose and inner half of the eyebrow could be raised upwards and to the left, for the better inspection of the ethmoid and frontal sinuses. The whole right upper jaw, palate bone, nasal bone, and part of the malar were now removed in one mass. (Fig. 4.) For cutting through the malar bone into the spheno-maxillary fissure a Gigli saw was used; for dividing the hard palate a keyhole saw. Elsewhere all separations were effected with a knife or bone-cutting forceps. It was not possible to leave the orbital floor or periosteum, as both were invaded. The "suspensory ligament" of the globe was not encountered—the eye rested on nothing but the orbital fat. The growth had invaded the right ethmoid, which, with the lacrymal bone, was now entirely removed up to the cribriform plate. The sphenoidal sinus and spheno-maxillary fossa were found to be free from disease. The attachment of the superior oblique pulley was not interfered with, and the soft palate was left. The cavity was swabbed everywhere with solution of zinc chloride, 40 grains to the ounce. The skin flaps were replaced and sewn up, and for 48 hours the cavity was kept plugged with wide ribbon gauze.

FIG. 3.

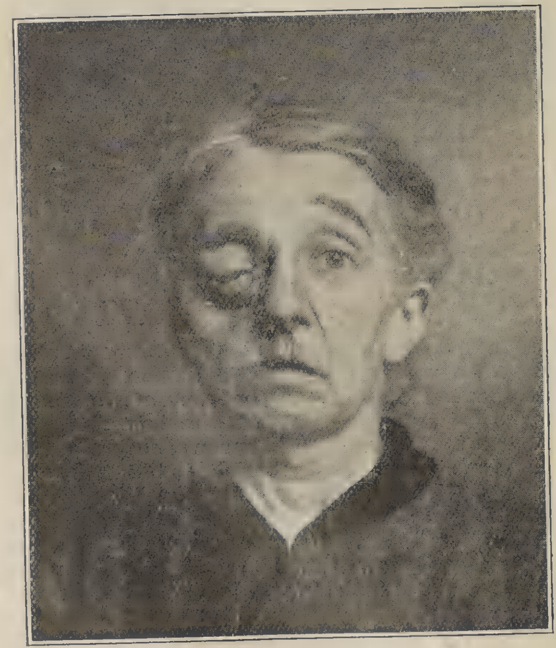


Appearance of the patient four months after first and shortly before second operation.

FIG. 4.

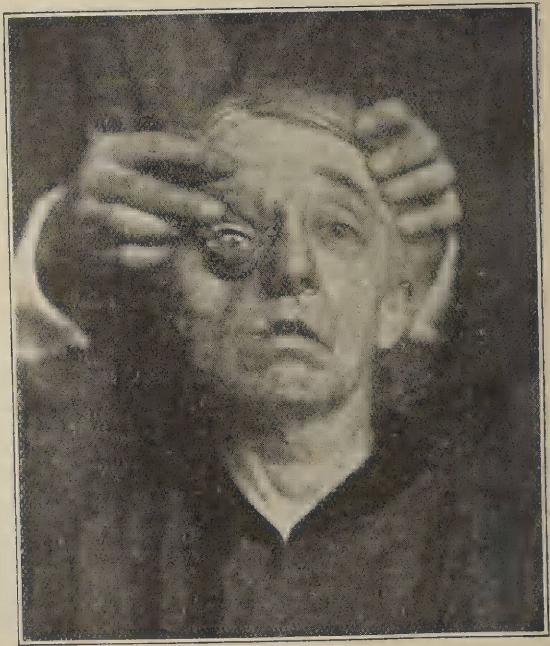
The upper jaw and adjacent bones removed at the second radical operation. The growth has rendered the identity of this unrecognisable, were it not for the teeth. About two thirds actual size.

FIG. 5.



Patient after operation. Shows the ptosis and inability to raise the eyebrow on the affected side.

FIG. 6.



Shows how the globe has dropped, but there is no diplopia.

Subsequent history.—Never at any time did the temperature exceed 99·8° F. nor the respirations 24. On the third day a marked conjunctival chemosis appeared. This was attributed to the great mechanical circulatory and lymphatic interference; and a leech on the upper eyelid cured it. But on the fifth day it reappeared, and simultaneously a brawny semi-fluctuating swelling was found over the right cheek, just in front of the ear. Incision evacuated from this an ounce of the foulest pus I have ever smelt; all the while the temperature, &c., remained normal. The chemosis now gradually disappeared. As the union of the incisions became complete, and before removal of the stitches, the skin for an area of 1 in. by ½ in., at the apex of the flap, just below the inner canthus, sloughed. Whether or not a plastic operation be undertaken later to close this opening, it has meanwhile provided a most convenient route through which to irrigate the upper part of the cavity. The eyebrow incision divided part of the origin of the levator palpebræ superioris and anterior belly of the occipito-frontalis muscles. Hence there are partial ptosis and inability to raise the eyebrow on that side. (Fig. 5.) An obturator with dental plate is being made under the direction of Mr. J. F. Colyer.

A curious feature of the case is that, although the eyeball has dropped a little, there is perfect vision with either eye separately (proving that both eyes are used), and no diplopia when using both eyes (Fig. 6); presumably an unconscious overaction of the intact extrinsic muscles compensates for the displacement of the globe. The photographs, which are published with the patient's consent, were kindly taken by Mr. J. W. Harrison; and the microphotograph (Fig. 2) by Mr. A. Cornell, of Tonbridge, with the super-microscope, without an enlarging camera, the invention of Mr. F. Davidson, 29, Great Portland-street, London, W.

Harley-street, W.

SPINAL ANÆSTHESIA IN 43 SUPRAPUBIC PROSTATECTOMIES.

BY H. M. PAGE, F.R.C.S. ENG.,
ANÆSTHETIST TO GUY'S AND THE WEST LONDON HOSPITALS.

I HAVE found spinal anæsthesia of great assistance in many genito-urinary operations, such as malignant disease of the bladder, lithotomy, some cases of lithotrity, extensive perineal fistulæ, &c., but in this paper I have only included suprapubic prostatectomy. A report on this one particular operation—performed, as it always is, on men who are all of advanced or great age, and in many instances suffering at the time of operation from the same kind of constitutional complications—is of a greater value for the comparison of spinal with general anæsthesia than if different operations, ages, conditions, and diseases had been included.

The victim of enlargement of the prostate gland is not only frequently of great age, but often presents evidence of organic degeneration, such as inadequately acting renal tissue, degeneration of the vascular system, emphysema, and bronchitis. The question of anæsthesia may therefore present a serious problem both as to the immediate result and ultimate recovery.

The commonest causes of death following suprapubic prostatectomy are shock and hæmorrhage, suppression of urine, pulmonary complications, and paralytic distension of the bowel.

From my experience in the administration of both general and spinal anæsthesia for this and many other kinds of operations I have come to the following conclusions. General anæsthesia administered for prostatectomy, which during the enucleation of the gland must be deep enough to relax the abdominal muscles, does not prevent shock. It tends rather to increase the amount of hæmorrhage if ether be the drug employed, and the risk of the supervention of urinary and intestinal complications: possibly it tends to increase pre-existing pulmonary troubles. Successful spinal anæsthesia, however, practically prevents shock, and even in cases where the spinal block is not perfect the operative shock is greatly diminished. The risk of the supervention of suppression of urine is smaller. This is principally due to the fact that the patient can be given fluids and stimulants by the mouth much sooner than after general anæsthesia, and partly to the absence of the effect of the general anæsthetic drug on the cellular tissues of the body. Any pre-existing pulmonary troubles are less likely to be increased. I may also add, as I cannot give an opinion on the subject myself, that a surgeon, who has used both general and spinal anæsthesia in a large number of prostatectomies, tells me that though distension of the bowel may occur after either, he considers it occurs less frequently after spinal anæsthesia.

The mental shock which some patients experience, due to being conscious during the operation, is, I am sure, a matter to be seriously considered. Fortunately this can be eliminated without practically losing any of the advantages claimed for spinal anæsthesia. Nitrous oxide and oxygen can be given during the operative interference, and in the absence of reflex stimulation this is comparatively easy. Personally I should always recommend the administration of these gases if the patient expressed a wish for unconsciousness or showed signs of nervousness.

The method I use is as follows. A previous subcutaneous injection of morphia or omnopon and atropine with or without scopolamine is given. I inject in the second lumbar space in the middle line with the patient lying on his side, using Barker's needles and his internal cannula. The drug used in all these cases was novocaine. In the first 21 cases I used a solution weighted with mannitol. I have given up using weighted solutions altogether. In the last 22 cases the unweighted 5 per cent solution with suprarenin borate, as made by the Saccharin Corporation, was used. The dose of this last solution for these cases varies from 2 to 2½ c.c. according to the age, size, and condition of the patient. Raising the buttocks slightly and flexing the thighs on the abdomen immediately after the patient is turned on to his back tend to raise the height of the anæsthesia even with unweighted solutions of novocaine or stovaine. The head is, of course, kept slightly raised at the same time.

The advantages I would claim for the use of the unweighted solution, instead of the solution purposely made heavier than the spinal fluid, are as follows. Temporary collapse is met with in a certain proportion of cases after intrathecal injection of any of the drugs used to produce spinal anæsthesia. Should this occur it can be treated by raising the patient's legs and lowering his head, and this is the most rapidly effectual treatment. With the use of this solution the foot of the bed can be raised on blocks immediately the patient has been put back there, and if he has to be carried up or down stairs after the operation this can be done with the head dependent.

In the cases reported here no failure to obtain muscular relaxation or analgesia occurred. Anæsthesia, though slow to appear in 3 cases, was perfect eventually in 41 cases out of the 43; in the 2 others there were muscular relaxation and analgesia of the bladder. 34 of the cases were operated on without any general anæsthesia. Nitrous oxide and oxygen were given to 4 cases for prevention of mental shock, the spinal anæsthesia being perfectly good. In 3 cases a little general anæsthesia was given during the skin incision, after which it was withdrawn and no more given. These 3 patients were completely conscious when the skin was being stitched up at the end of the operation. The skin was then completely insensitive; therefore they were cases in which the anæsthesia came on more slowly than usual. In 2 other cases a little general anæsthetic was given during the skin incision and stitching up only, none being given during the opening of the bladder or enucleation, muscular relaxation and bladder analgesia being present.

Personally I should advise anyone beginning to use this method to aim at getting anæsthesia with the minimum dose of the drug likely to produce it in the particular case, and to risk having to give a very little general anæsthetic to supplement it.

The ages of the patients in this series were—

1 case aged 94 years	Recovered.
1 ,, ,, 90 ,, ...	,,
4 cases over 80 ,, ...	All recovered.
14 ,, between 70 and 80 years... ...	,, ,,
20 ,, ,, 60 ,, 70 ,, ...	1 died.
3 ,, ,, 50 ,, 60 ,, ...	1 ,,

In a large majority of the cases I was asked by the surgeon to give spinal anæsthesia for special reasons, such as great age, vascular degenerations, low specific gravity of urine, emphysema, and bronchitis. Personally, therefore, I should claim this series, from the point of both surgeon and anæsthetist, as a test of average recovery to be rather an exacting than a favourable one. Of these 43 cases 41 recovered, the abdominal wound being healed and the urine passed naturally by the urethra. Two cases died.

1. Patient aged 65. At the time of operation he was suffering from uræmia. He recovered normally from his spinal paralysis and was no worse at the end of the operation than before, and remained no worse for two days, when vomiting and diarrhœa came on. The post-mortem record says: "Secretory tissues of kidneys practically non-existent."

2. Patient aged 53. He recovered normally from the spinal injection and operation. Did perfectly well for ten days, when an attack of acute lobar pneumonia (P.M.) came on and he died in a few days.

These two cases have no bearing on the question of anæsthesia. The first, as a rule, would have been a suprapubic drainage only and therefore not have got into statistics as to prostatectomy at all. The second was an accident occurring in a most favourable case for prostatectomy, and occurring too late after the operation to have anything to do with the question of anæsthesia, whether spinal or general. I have included them as I have here given all the cases in which I have used spinal anæsthesia for this operation.

There was no case of permanent sequela following the spinal injection. There are here 41 complete recoveries out of 43 cases. Taking into consideration the causes of death of the two cases that died, I would suggest that this is really a better average recovery than it appears.

I am particularly indebted to Mr. John Pardoe for being able to make this report, as the very large majority of the cases were his, including the patient aged 94, and I take this opportunity of thanking him for his help and encouragement. Neither of the two cases that died was his. My thanks are also due to members of the staff of Guy's and the West London Hospitals who have given me cases.

Welbeck-street, W.

A NOTE ON

TUBERCULIN ADMINISTRATION AND GRADUATED LABOUR.

By EDGAR TAUNTON, M.B. Lond., F.R.C.S. Eng.,
LIEUTENANT, R.A.M.C.; LATE SENIOR MEDICAL OFFICER, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR, ISLE OF WIGHT.

Patients admitted to the Royal National Hospital, Ventnor, undergo the ordinary open-air sanatorium treatment with rest or systematically graded exercise according to the state of the case. A part of the accommodation of the hospital (about a fourth) is, however, set apart for prolonged treatment of selected cases by a course of graduated labour. After selection these patients are on probation for a period of not less than four weeks, and if that term is passed satisfactorily they are taken in as "workers" to the special working blocks, where they remain until they leave the hospital.

Tuberculin has been carefully administered in some of the most promising of these selected "workers" by the intensive method, either "B.E." or "T.R." Slight reactions were occasionally observed. In the rare cases of prolonged reaction the use of tuberculin was discontinued.

It has seemed desirable to the medical staff of the hospital that some definite opinion should be arrived at as to the value of tuberculin in such cases (*a*) in shortening the duration of treatment; (*b*) in increasing the ability to do work; (*c*) in improving the general nutrition; and (*d*) in ensuring better after-results. For this purpose an examination of the records of 300 patients who passed through the "working blocks" between April, 1912, and March, 1914, has been made and the after-histories of about 60 per cent. of these cases have been with some difficulty obtained.

The course of graduated labour is for convenience divided into five grades of work, but in practice there is no abrupt transition from grade to grade, and it might be more nearly accurate to speak of ten or more grades, the point to grasp being that it is not a rigid system but a flexible one, adaptable to the needs of individual cases under constant medical direction and supervision.

Disturbances of temperature are a matter of prime importance in any consideration of the progress and treatment of cases of pulmonary tuberculosis, and here they have to do with the following. 1. The primary selection of cases for the working blocks. 2. The result of the probation of selected cases. 3. The further selection of patients for tuberculin administration is determined by the absence of such disturbances. 4. Ability to do work and the rate of progress from grade to grade of work are in relation to their absence or occurrence. 5. The duration of treatment itself is very largely a question of the absence of such disturbances and of their extent and duration when they occur. They involve rest, the cessation of work while they last, interruption of the course of graduated labour, and loss of time. The introduction, therefore, of a possible disturbing factor like tuberculin administration has to be justified by results or its employment is unwarranted.

Gain in weight if taken as an index, not as a measure, of improved nutrition is a sensitive and fairly reliable guide if considered along with other things such as the grade of work. As the observations are systematically taken their evidence is included.

After-results.—It can be stated without fear of contradiction that the object of treatment in sanatoriums is not so much for patients to be able to live in a sanatorium as that they should be able to live and work outside, and that the true estimate of results must have regard to these after-histories. It has also been suggested in the course of this inquiry that a true estimate of the value of tuberculin should be based upon these after-histories rather than upon the relatively short views of results by the time of leaving.

Analysis of cases.—Of 300 patients dealt with 71 were women workers and 229 men workers. Of the women 34, or 74 per cent., were given tuberculin, while of the men 44, or 19 per cent., had tuberculin.

Duration of treatment.—Women: (*a*) The average period of residence of the 34 women who had tuberculin was 202·4 days; (*b*) of the 37 women who had no tuberculin, 148·1 days; (*c*) the average increase in the duration of treatment required for tuberculin cases was 54·3 days, or an increased duration of treatment of 36·6 per cent.; and (*d*) in relation to the stadia of the disease the increased time required where tuberculin was used was as follows: Stadium I., 43·4 per cent.; Stadium II., 28 per cent.; and Stadium III., 33·8 per cent. Men: (*a*) The average period of residence of the 44 men who had tuberculin was 144·7 days; (*b*) of the 185 men who had no tuberculin, 125·2 days; (*c*) the average increase in time for tuberculin cases was 19·5 days, or an increased duration of treatment of 15·5 per cent.; and (*d*) in relation to the stadia of the disease, Stadium I. took 14·9 per cent., Stadium II. 22·4 per cent., and Stadium III. 11·7 per cent. longer treatment than those of the same stadia who had no tuberculin.

Ability to work.—The ability to do work has been estimated first according to the average grade of work reached while under treatment. This, however, required to be associated with the duration of treatment to give a true comparison. There is therefore also given a comparison of the average increase in grade of work per diem. Women: (*a*) The average grade of work reached by the 34 women who had tuberculin was 1·82, while that of the 37 women who had no tuberculin was 2·25, or 23 per cent. higher; and (*b*) the women who had no tuberculin showed in the average daily increase in grade of work the following percentage excess compared with those who had no tuberculin: Stadium I., 75 per cent.; Stadium II., 44 per cent.; and Stadium III., 61·2 per cent. Men: (*a*) The average grade of work reached by the 44 men who had tuberculin was 3·30, and that of the 185 who had none 3·61, or 9·39 per cent. higher; and (*b*) the men who had no tuberculin had daily excess increases in the grade of work in Stadium I. of 31 per cent., in Stadium II. of 27·1 per cent., and in Stadium III. of 29·1 per cent. compared with those of the same stadia who had tuberculin.

Gain in weight.—Here also the total average needs supplementing by data as to gain in weight in relation to duration of residence, and the mean daily gain is therefore given to enable a true estimate of progress to be made. Women: (*a*) Average gain in weight in 37 women without tuberculin, 11·9 lb.; in 34 women with tuberculin, 6·8 lb.; the increased gain without tuberculin thus equalling 5·1 lb., or 75 per cent. (*b*) Average daily gain without tuberculin in excess of those with it: Stadium I., 122·7 per cent.; Stadium II., 108·3 per cent.; and Stadium III., 100 per cent. Men: (*a*) Average gain in weight in 185 men without tuberculin, 13·5 lb.; in 44 men with tuberculin, 12·09 lb.; the increased gain without tuberculin being 1·4 lb., or 11·6 per cent. (*b*) Average daily gain without tuberculin in excess of those with it: Stadium I., 51·6 per cent.; Stadium II., 29·8 per cent.; and Stadium III., 3·8 per cent.

After-results.—As the result of inquiries sent to all of the 300 patients whose cases are under consideration 189 returns were sent in—61·6 per cent. of the cases treated with tuberculin ("T." cases), and 63·2 per cent. of those treated without it ("N.T." cases). The deaths recorded were not markedly different in the "T." and in the "N.T." groups—viz., 8·3 per cent. for both in women, and 12·8 per cent. "N.T." men and 16 per cent. "T." men. The chief difference was in accordance with what might have been anticipated from the progress of these cases in the hospital. Among the "N.T." cases 79·1 per cent. of the women and 71·1 per cent. of the men were reported as "able to do their work," while of the "T." cases only 50 per cent. of the women and 56 per cent. of the men could do so. To put it another way, adding together the men and women, while of the "N.T." cases 26·9 per cent. were unfit for work or dead, of the "T." cases 46·9 per cent. were so conditioned. Upon dividing the cases into two groups—viz., those who left in the first, and those in the second half of the period—a similar difference in the after-histories in favour of those who had had no tuberculin was found in each of the groups taken separately.

Summary.—The answers which the medical staff of the hospital sought to elicit from a consideration of these cases are given for these cases, and, under the conditions mentioned, with sufficient clearness to enable a definite opinion to be formed: 1. The administration of tuberculin to selected phthisical workers does not shorten, but, on the contrary, it lengthens, the duration of treatment. 2. The use of tuberculin does not increase the ability to do work. It appears not only to delay the improvement in working ability, but it also diminishes the ultimate ability achieved by a more prolonged course of treatment. 3. So far as gain in weight and the rate of gain enable one to judge, the administration of tuberculin is detrimental to the nutrition of patients to whom it is given under these conditions. 4. The after-results in fitting patients to do their work after leaving the hospital in these cases are less favourable where tuberculin has been used than in the cases where it has not.

Tidworth.

CROWNHILL CONVALESCENT HOME, NEAR PLYMOUTH.—The annual meeting of the subscribers to this home was held recently under the presidency of Earl Morley. The medical report stated that during 1914 the patients admitted numbered 236. Lieutenant-Colonel A. B. Soltau, the honorary physician, being away on war service, the duties had been performed by Dr. E. Lawrence Fox. The financial statement was satisfactory.

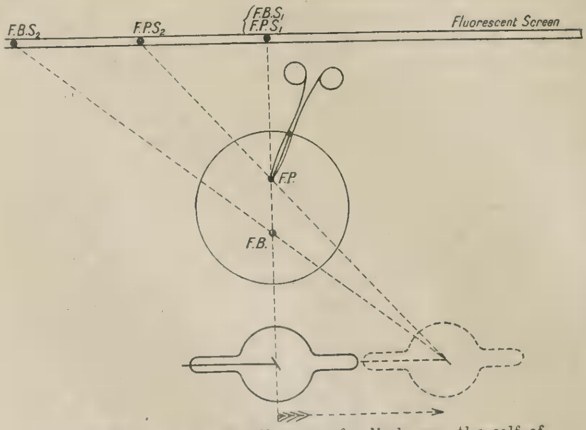
REPORT ON A FEW CASES ILLUSTRATING THE REMOVAL OF FOREIGN BODIES ON THE X RAY TABLE.

BY JOHN R. CALDWELL, M.B., CH.B. ST. AND.,
LIEUTENANT, ROYAL ARMY MEDICAL CORPS (SPECIAL RESERVE).

IN a recent article on this subject[1] the more routine adoption of a method of removing foreign bodies under the direct guidance of the X rays was advocated. A description in brief of the method employed at the Baltic and Corn Exchange Hospital, Calais, was then given, and it has occurred to us that an account of a few cases might add to the value of the communication.

For the benefit of those who have not given the subject of radiography special attention it may be well, as a preliminary, to recapitulate a few facts concerning the rough localisation of foreign bodies in situations not demanding precise and detailed measurements. In our recent article we have stated that it is possible to obtain much information during the course of a surgical operation performed upon the radioscopic table by a slight movement of the X ray tube. Let us suppose that a foreign body in the calf is to be removed. The object is first "centred." The incision is made directly over it, or as nearly so as is consistent with a safe approach. The skin, superficial fascia, and deep fascia are divided, and then the light is turned off and the X rays switched on. Guided by the screen, closed pressure forceps are pushed a little way into the tissues towards the foreign body. The tube is now moved to one side and the relative movements of the shadows cast respectively by the foreign body and the point of the forceps noted. Should the former seem to move farther than the latter then the forceps have to be pushed still deeper. The reason for this will be readily understood by reference to this simple and self-explanatory diagram. (Fig. 1.)

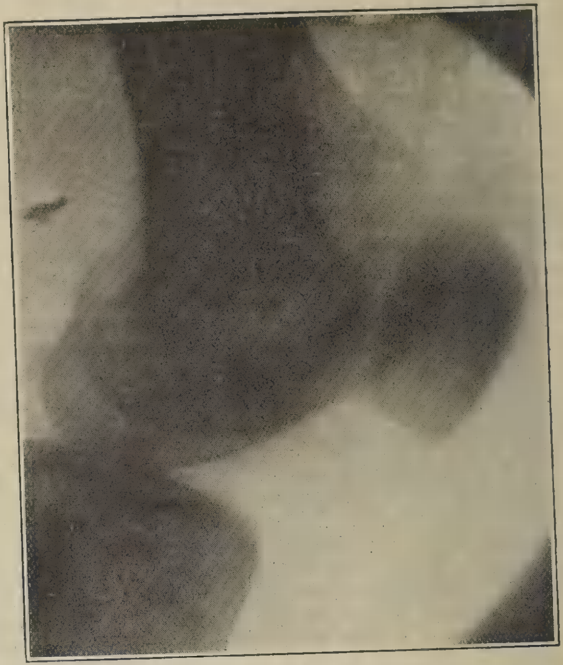
FIG. 1.



The circle represents the diagram of a limb, say, the calf of the leg, in section, in which F.B. represents the foreign body and F.P. the forceps point. Then F.B.S. and F.P.S. represent the shadows respectively of the foreign body and the forceps point on the fluorescent screen when the tube is situated vertically under the foreign body. When the tube is moved to one side in the direction of the arrow the corresponding shadows are represented by F.B.S.$_2$ and F.P.S.$_2$

In the removal of minute foreign bodies the greatest difficulty is sometimes experienced; and while, in many cases, these may be well left alone, yet it sometimes occurs that it is most advisable to remove them. Of this nature is the case that follows. (Fig. 2.) A private of the 2nd Chasseurs à pied was wounded at Dixmude on March 17th by a small piece of bullet mantle, probably from a ricochet. There was a punctiform wound in the outer side of the left thigh four inches above the patella. As the radiogram shows the sharp metallic fragment which caused it had penetrated deep into the popliteal space. An incision was made in the line of the tendon of the semitendinosus, and dissection was carried on until the popliteal vessels were displayed. The dissection towards the fragment was guided by frequent screening; but, of course, none was done under the rays, except the final extraction of the minute projectile. The artery having been recognised by sight and being kept under the finger when the rays were switched on, a pair of closed forceps was introduced and gently pushed through soft tissue till the fragment was reached. The foreign body, which was sticking in the sheath of the popliteal artery, was then gently grasped and removed. There was no after-trouble.

FIG. 2.



Showing a small foreign body in the sheath of the popliteal artery.

The minuteness of the foreign body makes the case seem almost trifling, yet the consequence of the presence of such a sharp metallic fragment in the proximity of the artery might have been very serious.

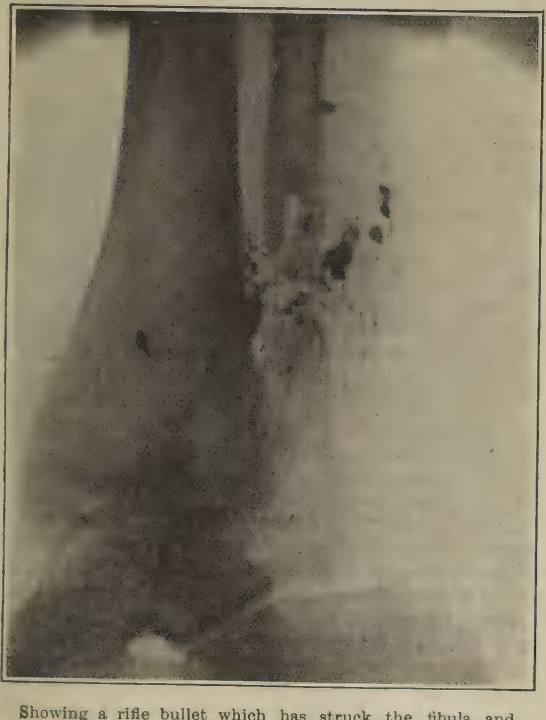
Again, minute foreign bodies may act as sequestra and prevent healing, as in the case illustrated in Fig. 3. The patient was a cyclist of the 1st Carabiniers and was wounded, eight days after the war began, at Warumme, near Liége. He was taken to the Red Cross Hospital there, and carried thence in the retreat, first to Louvain and then to Ghent, where he was operated upon; then to Ostend, to Duinbergen; then to England, to Hastings, where he was operated upon for the second time; then back to his depôt in France, whence, on March 19th, he was sent to us for his third operation. He had pain which incapacitated him in his left lower leg. The old operation scars ran vertically upwards from behind each of the malleoli. There was a dry sinus in that over the tibia. The operation consisted of incisions upwards in the lines of the old ones and removal of the metallic fragments under the X rays. One piece was found lying at the bottom of the sinus, and after it was extracted the sinus itself was carefully excised. Both wounds were sutured without drainage and healed by first intention, and the patient was discharged a fortnight after admission, cured.

---

[1] THE LANCET, April 24th, 1915, p. 854.

The most difficult cases are those in which a foreign body lies embedded in muscular tissue without any intimate relation to bone. The region is, as it were, uncharted. Plates demonstrating such cases are at the Baltic Hospital rarely taken, as the projectiles are removed on the X ray table without any more ado; but our view as to the difficulty is supported by the number of such patients we have had sent to us showing large operation scars following a prolonged but fruitless search. By the direct method of operating the possibility of working along the wrong muscular plane is obviated and difficulties are reduced to a minimum.

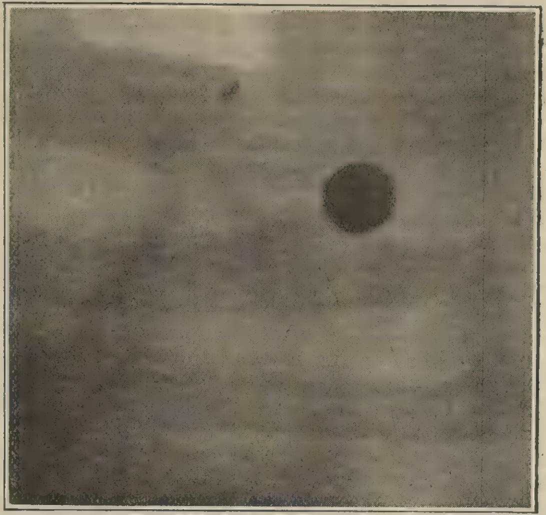
FIG. 3.



Showing a rifle bullet which has struck the fibula and exploded into minute fragments. (Longmore quotes Busch to the effect that rifle bullets on striking bone may "actually become melted and divided into numerous slug-like particles, and that this adds greatly to their destructive effects in wounds.")

A lame convalescent returned to hospital will serve as an example of the trouble caused by a bullet lying deep in muscles, even though the wound may have healed. He was wounded in the back on Oct. 22nd of last year and received treatment at two hospitals in England, but the bullet was not removed at either. On his return to the front he was unfit for duty owing to pain on walking. He also described a loss of sensation over the front of his left thigh. On account of these symptoms he was sent to us for extraction of the foreign body. A stereogram, not reproduced, showed a bullet pointing downwards lying deep in the muscles of the back on the left side in the angle between the iliac crest and the vertebral column. At the operation a small longitudinal incision was made at a somewhat higher level than the situation of the bullet. The reason for making it there was to allow of the base of the bullet being grasped. The tendon of the latissimus dorsi was cut in the line of the first incision and the fibres of the erector spinæ were exposed. Guided by the rays these were split with blunt forceps, and the bullet, which was lying deep in the muscle, was grasped and extracted. The whole operation, as is usual, was only a matter of a few minutes. The patient was discharged a few days later free from pain and healed.

FIG. 4.



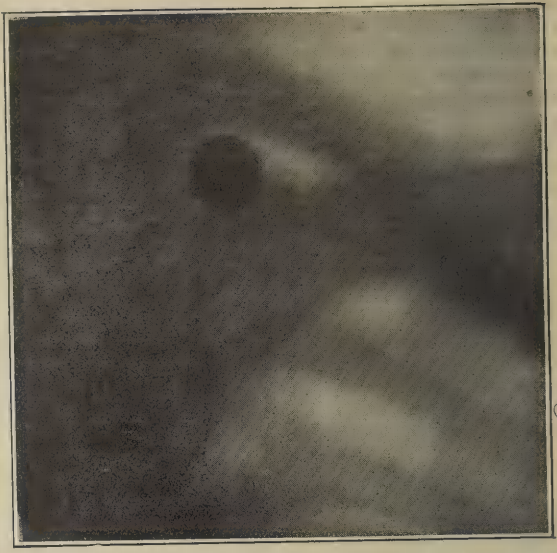
Showing a shrapnel ball (embedded in callus) that had been lying for four months *in situ*—viz., between the third and fourth ribs and on the pleura. It caused pain and incapacity and was removed by operation under the X rays.

The wide sphere of usefulness of "the direct method" is shown in the following three cases. In Fig. 4 a shrapnel ball is seen lying between the third and fourth ribs. The patient, who had been wounded four months previously at the battle of the Yser, was admitted here on Feb. 18th of this year. He complained of pain in movement of the right shoulder, but there was no shoulder lameness. There was a small scar in the posterior axillary fold about the level of the sixth rib. This had been the wound of entrance. The radiogram shows two things. One is the shrapnel ball between the ribs, four centimetres from the mid-line, and the other is that the fourth rib was broken and comminuted. Evidently the ball had passed slightly upwards through the axillary fold and between the scapula and ribs, grazing and breaking the fourth, and lodging in the space above it. Subsequently it was found that it had penetrated deeper, for it had passed forwards between the ribs and lay just on the pleura. At the operation, the arm being pulled up and out to get the scapula out of the way, a long vertical incision, four inches, was made through skin and fascia and also through the tendon of the trapezius. The subjacent muscles, the rhomboideus major and then the erector spinæ were split in the line of their fibres and well retracted. Then under the rays the deep hole thus made was probed with pressure forceps and the point of the forceps could be placed upon the ball with ease. The ball could not be grasped, however, and on switching on ordinary light the point of the forceps was found to be on bone. On making quite sure of this by repeated screening it became evident that this bone must be callus[2] occupying the width of the interspace. Thereupon the callus was chiselled away and the leaden shrapnel ball revealed. To get it out it was necessary to chip away a little of the rib, both above and below. That done it was lifted from its bed with the utmost gentleness lest the pleura should be damaged. The wound was partly closed, but a drain was left in. Unfortunately convalescence was delayed by some degree of sepsis which commenced a week later; but on March 16th the patient was fit for discharge to England practically healed.

We had one case which specially showed the inefficiency of ordinary methods of localisation as aids to extraction. On screening the region of the hip foreign bodies were seen, a bullet and its mantle. The bullet was the darker shadow, lying anterior to the great sacro-sciatic ligament. During its passage from the wound of entrance, which was three inches below the great trochanter, the mantle of the bullet had been stripped off, and was seen as a fainter shadow behind the acetabulum. The bullet was therefore just inside the pelvis, whilst the mantle was left lying rolled up in the dense fibrous tissue behind the joint. The patient was wounded in December, and the bullet and mantle were not removed till he came under our care in March. We first saw him, however, a day or two after his wound had been received, for he was sent to us by a French hospital for radiographic examination. The position of the bullet was then marked on the skin and located at a depth of eight centimetres. Armed with this information and with a plate, the French surgeon, a most competent operator, made an incision four inches long in the line of the great sciatic nerve. He searched fruitlessly for the bullet, and the patient after 66 days in hospital returned to duty. Eighteen days later, on March 11th, he was sent back to hospital on account of pain in walking, and there was tenderness posteriorly over the neck of the femur. On the 13th he was operated on for the second time, on this occasion at the Baltic Hospital. A three-inch incision in the line of the great sciatic nerve, and then splitting of the gluteus maximus in the line of its fibres were the initial stages of the operation. Then the rays were switched on, and by blunt dissection the bullet located. It was levered up from its bed by an elevator pushed gently under its lower pole and removed by forceps. The mantle was extracted without difficulty. When the soldier left the hospital a week later his wound was healed and his pain had gone.

The minimum of damage is done to the tissues by "the direct method." Of this fact the case illustrated by Fig. 5 affords a striking example. The story is a simple one. The man was wounded in the neck at Antwerp on Sept. 11th, but did not come into our hands until March 7th. He had been to England in the interval and his wound had healed, but he still had pain in his neck, and was sent to us on that account. The scar was an inch to the left of the sixth cervical spine. The X rays showed a shrapnel ball lying between the transverse processes of the first and second dorsal vertebræ. A vertical incision was made over it through the skin and the aponeurosis of the trapezius. The muscles were split in the lines of their fibres and then under the rays the forceps was inserted and the ball grasped and removed. Eleven days after he had been admitted the patient was discharged free from pain and healed.

FIG. 5.



Showing a shrapnel bullet lying between the transverse processes of the first and second dorsal vertebræ.

It has been urged by some that this method of operating holds considerable danger for the surgeon, but after six months of operating by it I may say, speaking personally, I have had no trouble. Working with the smallest diaphragm available it is possible to keep the hands almost always out of the "direct line of fire." We take the precaution to smear the nail-beds with flexile collodion before each operation. Two pairs of rubber gloves are worn, an outer thick pair which can be removed when the extraction is completed, and an inner thin pair for more delicate work.

During the past six months upwards of 132 wounded patients have been admitted to the Baltic Hospital with projectiles still lodged in the tissues. In many wounded by artillery several shrapnel balls or fragments of shell casing were present. In all except four instances the foreign body has been removed, and in the great majority this has been accomplished by operating directly under the X rays.

In conclusion, I wish to acknowledge my indebtedness to Dr. L. J. Picton (St. John Ambulance), surgeon and registrar, for his help in compiling these cases. My thanks are due also to Dr. H. R. Ramsbotham, B.R.C.S., and Lieutenant A. E. Chisholm, R.A.M.C., for their permission to publish two of the cases which were respectively under their care.

THE CHEMISTRY OF RICE-POLISHINGS.

BY HENRY FRASER, M.D. ABERD.,
DIRECTOR, INSTITUTE FOR MEDICAL RESEARCH, KUALA LUMPUR, FEDERATED MALAY STATES;
AND
A. T. STANTON, M.D. TOR.,
BACTERIOLOGIST, INSTITUTE FOR MEDICAL RESEARCH, KUALA LUMPUR, FEDERATED MALAY STATES.

IN 1911 we published evidence that beri-beri in Malaya is caused by the consumption of polished rice as the staple of diet, and that the substance or substances in rice-polishings and in unpolished rice which prevent the disease are soluble in alcohol and are decomposed by sodium hydrate. The experiments with sodium hydrate were referred to on page 74 of our report, but as one of the methods since employed by chemists who have sought to isolate the substance has involved the use of barium hydrate it is desirable that details of these experiments should now be given.

From a series of observations it was determined that fowls weighing from 1200 to 1400 grammes ordinarily consumed about 60 grammes of unpolished rice daily, and if fed on 60 grammes of polished rice they required in addition 5 grammes of polishings for the maintenance of weight and health. The polishings were passed into the crop once daily in the form of an emulsion in water.

In our experiments polishings were extracted twice with six times their volume of 0·3 per cent. hydrochloric acid. The polishings after extraction were tested and found valueless. Alcohol was added to the extract so as to bring the mixture up to the strength of proof spirit. The precipitate, which consisted of phytin, was rejected. The filtrate was nearly neutralised, concentrated at a low temperature, and its volume so adjusted that 30 c.c. contained the material soluble in proof spirit from 5 grammes of polishings.

Eighteen fowls were fed on polished rice and received once daily 30 c.c. of this solution. Their health was unimpaired, as is shown by Table I., which gives the weights in grammes of the first six fowls.

TABLE I.

Date.	1	2	3	4	5	6
7-8-10 ...	2095	1265	1550	900	1410	1105
11-8-10 ...	2140	1280	1695	850	1430	1160
18-8-10 ...	2100	1380	1655	905	1425	1075
25-8-10 ...	2060	1275	1625	915	1445	1070
1-9-10 ...	2050	1265	1660	935	1460	1100

Another lot of polishings was extracted in the same way and alcohol added to the extract as before. To the proof-spirit filtrate sodium hydrate was added so as to make a solution containing 0·3 per cent. of that substance. The precipitate was collected, and the amount of it obtained from 5 grammes of polishings was given once daily to each of six fowls fed on polished rice. The results of this experiment during 12 days are shown in Table II.

TABLE II.

Date.	1	2	3	4	5	6
5-9-10 ...	1440	1615	1575	1565	1195	1385
12-9-10 ...	1340	1595	1340	1565	1255	1325
17-9-10 ...	1265	1555	1335	1400	1215	1305

The filtrate was neutralised and evaporated at a low temperature until free from alcohol. The volume of the solution was then adjusted, so that 30 c.c. represented the non-alkali precipitable material from 5 grammes of polishings. Each of six fowls on polished rice received 30 c.c. of this solution once daily. The results of this experiment during 12 days are shown in Table III.

TABLE III.

Date.	1	2	3	4	5	6
5-9-10 ...	1520	1620	1555	1565	1260	1410
12-9-10 ...	1450	1505	1320	1470	1250	1490
17-9-10 ...	1405	1420	1180	1380	1200	1410

The fowls in neither of these two groups did well and most of them lost weight rapidly. On further examination it was found that 0·3 per cent. of sodium hydrate did not effect complete precipitation. From this it was inferred that the active substance was either separated into two parts or that it has been decomposed by the alkali.

It was found that by making the proof spirit alkaline to the extent of 0·5 per cent. sodium hydrate precipitation was complete. An experiment was then carried out in which fowls on polished rice received daily the alkaline precipitate obtained in this way from 5 grammes of polishings (Table IV.).

TABLE IV.

Date.	1	2	3	4	5	6
14-9-10 ...	1430	1145	1345	1030	1340	1595
20-9-10 ...	1320	1010	1290	960	1180	1360
27-9-10 ...	1255	915 P.	1170	845	1065	1275
29-9-10 ...	—	—	P.	—	—	P.
1-10-10 ...	—	—	—	—	P.	—

P. = polyneuritis.

It soon became apparent that the fowls were not doing well and the occurrence of polyneuritis ended the experiment. In view of the preceding results it was unnecessary to carry out an experiment with the alkaline filtrate. The inference from these experiments was that sodium hydrate in weak solution destroyed the active substance.

These experiments were not designed to test the destructive effect of alkali, but were attempts to isolate the active substance, and the results were surprising in that so weak an alkali should destroy a body which is not affected by boiling. Various other methods were tried without success.

Funk continued these researches, and in 1912 announced that he had isolated an organic base which he called "vitamine" and to which he attributed curative properties. He extracted polishings with acidulated alcohol and then removed the alcohol by concentration *in vacuo*. The residue was mixed with water and freed from fat. It was then acidulated with sulphuric acid and excess of phospho-tungstic acid added. The precipitate was removed and the filtrate, freed from phospho-tungstic acid, was found to be ineffective. He then mixed the precipitate with barium hydrate and removed the barium phospho-tungstate. The filtrate, he stated, contained ammonia and smelt of methylamine. This suggested to us, in view of our experience, that he had decomposed the active substance. The further treatment to which he subjected the odoriferous filtrate strengthened that view, and we were unable to reconcile his results with our own. From subsequent publications it is learned that he became less certain of the soundness of his results, and in 1913 he stated that two substances were necessary to effect a cure; but a paper which has just been published by Drummond and Funk confirms our findings, for they state that "we have ourselves failed to isolate the curative substance which occurs in rice polishings. It is apparently decomposed during the fractionation and all trace of it is lost." Through the complicated processes to which the extract was subjected by them it is unnecessary for us to go, save to express the belief that the decomposition was, in part at least and perhaps entirely, due to the use of baryta.

The existence of "vitamine" in the sense that Funk employed that word is therefore disproven. The word itself is not objected to and may be applied to the substance when it is isolated, but the premature publication of results which, on the findings of the writer himself, are subsequently shown to be erroneous creates confusion and retards progress. At the present day the problem is no nearer solution than it was four years ago, nor is progress likely to be made until improvements are effected in the methods employed by chemists in this work; those now employed are crude and imperfect.

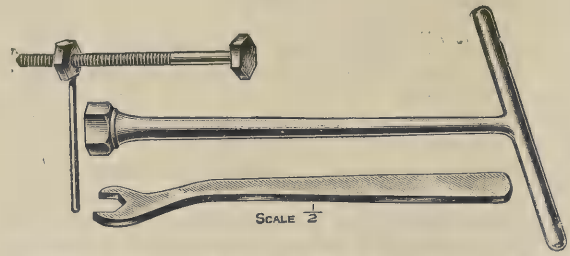
Kuala Lumpur.

A BOLT FOR THE TREATMENT OF FRACTURES.

By CUTHBERT WALLACE, M.B., B.S.LOND., F.R.C.S. ENG.,
SURGEON, ST. THOMAS'S HOSPITAL; JOINT LECTURER ON SURGERY IN THE MEDICAL SCHOOL.

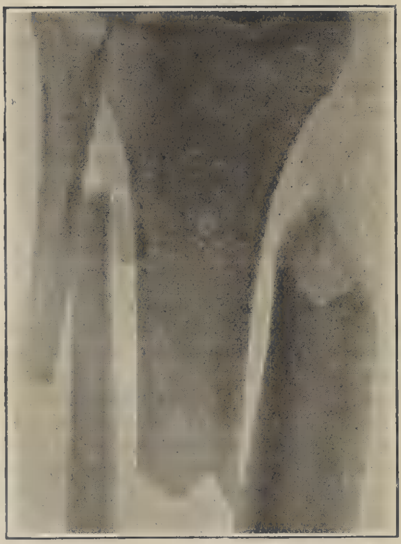
THE plating of a long oblique fracture presents some difficulties. To ensure complete fixation two plates are required, one on either side of the bone at the opposite ends of the fracture. Even if only one plate used the shaft of the bone beyond the end of the fracture must be exposed to allow the application of the plate. Some years ago I devised a bolt (Fig. 1) for the treatment of long oblique fractures and have found it useful in fractures which are only slightly oblique.

FIG. 1.



Showing the essential parts: 1. A bolt. 2. A nut with a soft wire brazed to one facet. 3. A flat spanner. 4. A clock-key spanner.

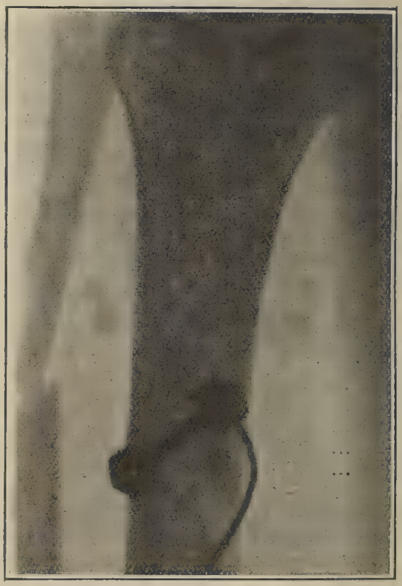
FIG. 2.



Shows a fracture before bolting.

The mode of application is as follows: The fracture is reduced. A hole is then bored through the centre point of the fracture with a Morse drill. The axis of the hole should be at right angles to the axis of the bone. If the fracture is not very oblique it is best to set the bolt somewhere near a right angle to the fracture. The hole should allow the bolt to pass easily. The bolt is pushed through till the end just emerges on the opposite side. (Figs. 2 and 3.) The nut is then taken up by the wire and held so that the bolt can engage when turned by the clock-key spanner. The bolt is then screwed home, rotation of the nut being prevented by traction on the wire. Very little force is necessary to bring about complete fixation of the fracture. When this is accomplished the protruding end of the bolt is cut off by a pair of screw-cutting forceps. The wire is then bent round the bone to the head of the bolt and the redundant part cut off. The object of leaving the wire *in situ* is that the nut can easily be withdrawn if it is necessary to remove the bolt when union has occurred. If the bolt passes obliquely to the axis of the bone-shaft the head can easily be housed by cutting away some of the shaft.

FIG. 3.



Same as Fig. 2, after bolting.

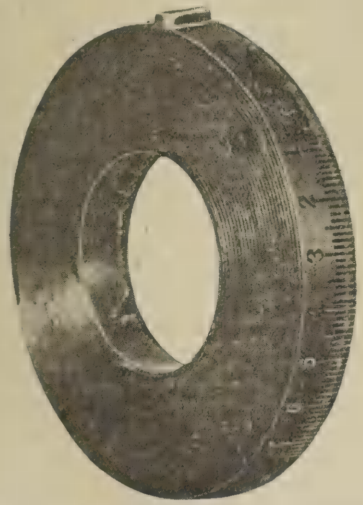
Clinical Notes:
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

SHELL WOUND OF THE LEFT SHOULDER; EXTRACTION OF FRAGMENT FROM THE NECK.

By J. B. Haycraft, M.B. Edin.,
LIEUTENANT, R.A.M.C. (TEMPORARY).

A private of the Guards was admitted on Nov. 3rd, 1914, with a shell wound on the back of the left shoulder, which he had received three days previously. The wound, which was oval in shape, with jagged edges, and about the size of a five-shilling-piece, was situated almost exactly over the back of the joint. The exposed muscle and fascia were greenish-black in colour, and there exuded a lot of brown-coloured foul-smelling fluid, together with bubbles of gas and broken-down blood clot. The shoulder, back, and left side of the neck were greatly swollen, and the skin over a wide area was discoloured, being of a bluish colour close to the wound, fading away to a yellowish-brown with an apparently raised edge. The head was held rigid, any movement of the neck causing severe pain. There was a great deal of dyspnœa, the patient having to be propped up in bed, and he could only swallow liquid food with difficulty. He had a high temperature and sweated profusely, showing signs of septic absorption. The wound was probed, but nothing was detected, neither could anything be felt on palpation of the neck or back. Owing to the valvular nature of the wound the finger could not be inserted for any distance.



"Time train" of a German shell, exact size, extracted from shell wound.

Nov. 7th: The wound had been syringed out twice daily with hydrogen peroxide, and the patient's general condition was much improved. Œdema and discolouration were less marked, and breathing was much easier though there was still considerable difficulty in swallowing. A localised swelling was now apparent in the left supraclavicular space; it was slightly red, extremely tender, and on percussion yielded a resonant note.

Under chloroform an incision about 2½ inches in length was made over the swelling in the posterior triangle of the neck. Its direction was diagonal from above downwards and inwards. On dividing the deep fascia some gas and foul-smelling fluid escaped, and on exploring with the finger a large cavity was found in which a foreign body could be felt at a considerable depth from the surface. The incision, being too small to permit of its extraction, was enlarged, the external jugular vein being divided between forceps and ligatured. The body removed proved to be the circular movable "time train" of a German shell. It is situated just behind the apex of the shell, and can be moved round regulating the time at which the shell will explode after being fired. It weighed 6¼ oz. and was lying in a slanting direction pressed up against the great vessels, œsophagus, and prevertebral muscles. A drainage-tube and gauze packing were introduced.

Nov. 8th to 16th.—The wounds were syringed through twice daily with hydrogen peroxide and sloughs removed. The swelling and discolouration gradually disappeared and all difficulty in breathing and swallowing was relieved. The patient was discharged on Nov. 16th, the wounds being practically clean.

The points of interest in the case are: (1) The small size of the entrance wound compared with the diameter of the piece of shell; (2) the presence of so large a foreign body in the neck which could not be detected by palpation; and (3) its close proximity to several vital structures without proving fatal. The illustration represents the actual size of the object.

A CASE OF INTESTINAL OBSTRUCTION DUE TO A GALL-STONE,
IN THE COURSE OF WHICH NUMEROUS GALL-STONES WERE VOMITED.

By A. R. Neligan, M.D. Lond., M.R.C.S., D.T.M. & H. Cantab.,
PHYSICIAN TO THE BRITISH LEGATION, TEHRAN.

Cases of intestinal obstruction due to gall-stones are recorded in medical journals fairly frequently, but the vomiting of gall-stones must be, I think, an event of some rarity. However that may be, my small library makes no mention of it, and so I venture to describe the first case of which I have heard.

The patient, an enormously fat Russian woman, 55 years of age, and of alcoholic habits, was seen early on August 14th, 1914, for diarrhœa, vomiting, and abdominal pain. These symptoms had come on during the night, and were ascribed to a surfeit of grapes on the previous day. There seemed to be no doubt of this, for, before I left the house, she vomited a quantity of grape-pips and skins, a fact which moreover suggested that her stomach was dilated. A large drink of warm alkaline water was prescribed in order to wash out the stomach, to be followed by calomel in fractional doses. In the evening I was called to see the patient again. The diarrhœa had stopped before midday—in fact, no flatus had been passed since that hour; the vomiting was as bad as ever and the vomit consisted of bile and mucus. The pain was coming on in severe paroxysms; it was felt all over the abdomen, but was particularly severe in the right hypochondrium. The abdomen was more distended than in the morning; nothing definite could be felt in it or per rectum.

A fact in the patient's previous history now assumed importance—namely, that some six months before I had seen her in consultation on account of prolonged fever and obstinate constipation. She had then an enlarged and tender liver; continuous with the lower border of the right lobe and extending to the navel was a large tender mass. There was a leucocytosis of 25,000. The diagnosis lay between abscess of the liver and cholecystitis. An operation was recommended, but was refused. The patient slowly recovered and the tumour disappeared as I was afterwards told.

From her present symptoms I therefore came to the conclusion that she was suffering from biliary colic with reflex paralysis of the bowel. The usual remedies were ordered as well as large enemata. During the next day the vomiting continued and the vomited matter took on a fæcal odour; the pain increased, the abdomen became greatly distended, the pulse weaker and more rapid. The bowels had not acted in the night, nor had flatus been passed. While I was in the room that morning the patient vomited into a metal vessel, and I was attracted by a sound which suggested that a charge of buck-shot had been fired into it. On examination a number (about 30) of small faceted gall-stones were found, the largest of which was about the size of a dried pea. The patient said she had vomited a smaller number of similar stones some hours previously.

It was now evident that the woman had intestinal obstruction. Further, it seemed reasonable to suppose that no other cause having been found, the obstruction was due to a gall-stone which had escaped from the biliary passages into the bowel. As she was obviously going down hill I advised that laparotomy should be done. This was refused by her medical attendant on the ground that she ought to have had an operation six months before, but had got well without one. This seemed rather curious reasoning at the time, but later events justified it.

On the morning of August 16th the patient was still weaker. A variety of enemata had been tried without result, but a little flatus had been passed. The abdomen was still more distended. That evening I was called to see her again. I found her looking better and wearing an almost triumphant smile. Apparently she had felt very ill during the afternoon and had asked her master to give her some champagne. He had sent her a bottle. She drank a glass and felt better and had a strong desire to go to stool. She passed flatus, liquid fæces, and something hard which made such a noise in the utensil that "she and everyone else were frightened." This turned out to be a gall-stone. Unfortunately, the family's curiosity had been too much for them and the stone had been broken with a hammer. What was left showed that it must have been roughly round in shape and three centimetres in diameter; it must have weighed about 16 grammes. There was one large facet. The stone consisted of cholesterol with an external coating of phosphates 1 millimetre thick.

The patient made a good recovery, and her abdomen shows no signs of the stormy events which had taken place inside it. She has now been quite well for three years; this in spite of the fact that she looks upon champagne as a sovereign remedy and does not at all approve of the Russian campaign against vodka. Surely Nature has never made a more determined or a more successful effort to get rid of gall-stones.

SECTION OF PATHOLOGY.

Tyrosine as an Aid in the Demonstration of the de novo Origin of Living Organisms.—Aneurysm of the Left Ventricle.—Arc Light Method of Isolating Typhoid Organisms, and Agglutination Method.

A MEETING of this section was held on May 4th, Dr. F. W. ANDREWES, the President, being in the chair.

Dr. H. CHARLTON BASTIAN read a paper on the Importance of Tyrosine as an Aid in the Demonstration of the Present-day *de novo* Origin of Living Organisms. He said that the incredulity with which the results of experiments showing the occurrence of "spontaneous generation," called by him "archebiosis," had been received had given rise to attempts to explain them away by one or other of three suppositions: (1) that the bodies found were mere simulacra or pseudo-organisms; (2) that the organisms found were dead, and having pre-existed in the experimental solutions were killed by the sterilising process; and (3) that the alleged organisms had not really been taken from the tubes but had come from an impure pipette, or dropped from the atmosphere on to the microscope slide before the cover-glass had been applied. He adduced evidence to show that the last view was untenable. To dispose of objections (1) and (2), tyrosine had proved valuable since the use of a small quantity of a very dilute solution of this substance caused the living organisms that might be present to grow and multiply freely. Its effect was noted on the contents of tubes which were fairly ripe for examination—i.e., seven to nine months after sterilisation. From each tube that was opened a sample of the deposit was taken with a well-sterilised pipette, and then with another pipette about 20 drops of the sterilised tyrosine solution were added. The tube was then securely closed and again placed in the incubator or exposed to light. After three or four weeks each tube was opened again and another sample of its deposit was withdrawn, stained, and compared with the earlier sample. All of about 40 of these tubes that had been examined had shown a very remarkable increase in the number and size of the organisms. The unmistakable growth and multiplication of the organisms effectually negatived the suppositions that they were either simulacra or dead. When tyrosine was added to new tubes, however, every one remained sterile, which seemed to indicate some harmful effect of the tyrosine on the solutions. This result, though unexpected, told strongly against supposition (3).

Dr. R. HINGSTON FOX exhibited a specimen of Aneurysm of the Left Ventricle. The aneurysm projected from the apex of the heart and was about as large as a cricket ball. Over it the pericardium was adherent. The aortic valve showed sclerotic changes and a coronary artery some thickening of its walls. Both kidneys were enlarged, adherent to the perinephric fat, and contained calculi, one as large as a walnut. Some of the distended loculi contained pus, and one a yellow substance, of amber hue, which could be cut easily with the knife. No changes attributable to syphilis were found elsewhere in the body.

Professor G. DREYER and Dr. E. W. AINLEY WALKER demonstrated the Arc Light Method of Isolating Typhoid Organisms devised by the former.[1] Professor Dreyer said that the results of light on micro-organisms had been much confused with those of heat. Speaking of the powers of different parts of the spectrum, in this respect, he said that a great effect was caused by the ultra-red rays, but the maximum effect was shown by the ultra-violet. The intervening parts of the spectrum were less effective, gradually strengthening from red to the first part of the ultra-violet, but weakening somewhat at the violet. The effect of light on micro-organisms could be studied in detail by using clear glass, blue glass, quartz, or a solution of potassium bichromate. It was possible by means of selected light to isolate micro-organisms, even when this was impossible by ordinary bacteriological methods. Speaking of the application of the method to typhoid fever, he said that an emulsion of a large mass of fæces could be used, which was advantageous. Four drops of good size were then dropped on to a gelatine plate by a Pasteur pipette and rubbed well over its surface until almost dry. The middle part of the plate was then exposed to the light, the lateral parts acting as controls. With successive exposures of a few seconds more and more of the surface in sections was protected from the light, so that different parts of the plate were exposed for different periods. The electrode could be of iron, aluminium, platinum, gold, or silver, the last being preferable as far as had been found at present. This electrode closely apposed a hollow tube containing a smaller hollow tube. Cold water flowed in through the inner tube, impinged on the electrode, and flowed out through the outer tube. In this way a perfectly cold light was assured and fusing of the electrode safeguarded.

---

[1] THE LANCET, March 27th, 1915, p. 646.

Professor **DREYER** also demonstrated shortly the agglutination method which is associated with his name.[2] By it the temperature was kept constantly at 55° C., the culture was one of dead organisms, and consequently constant also. The advantages he claimed for it were that co-agglutination did not occur, that the end point of reaction was reached practically at the end of half an hour, and that a constant temperature and emulsion of organisms being employed the agglutinating powers of sera could be strictly comparable.

Dr. **AINLEY WALKER** said that the advantages of the arc light method were its rapidity, the large amount of material which could be examined, and the avoidance of the gradual dying out of organisms which occurred by using media. The agglutination method he considered to be certain and reliable, and an easy method of distinguishing an active case of typhoid fever from a case in which immunity had been attained. It allowed of a comparison being made between the agglutinating power of the patient's sera on succeeding days. The cultures could be used in very high dilution.

SECTION OF PSYCHIATRY.

The Thyroid Gland and Mental Disorder, with Especial Reference to Hypothyroidism.—Exhibition of Cases and Specimens.

A clinico-anatomical meeting of this section was held on April 28th at Claybury Asylum, by the courtesy of Dr. Robert Armstrong-Jones, under the presidency of Dr. F. W. MOTT, F.R.S.

Dr. M. **KOJIMA** read an interesting paper setting forth the results of examination of the thyroid gland in 110 cases of mental disorder, with especial reference to hypothyroidism. In this consecutive series all the ductless glands were carefully removed from the body, then freed from their surrounding tissue and weighed. The minimum average weight of the thyroid in the non-insane was 22 to 25 grm. In the average insane person the weight was much less—namely, about $16\frac{1}{2}$ grm. in males and 16·87 grm. in females, but there was considerable variation in the weights among the insane, especially in females. He considered that all these cases exhibited hypothyroidism. The weights of the external parathyroid in 41 cases varied from 0·01 to 0·07 centigramme. In a third of the cases four glands were found. The weight of the pituitary body seemed to have no relation to the nutrition of the body or to the form and duration of the insanity. The adrenals of the male were heavier than in the female, and there was no relation of their weight to that of the body. No definite conclusion could be arrived at regarding the weight of the reproductive glands in the male and female in relation to body weight or mental disease, except that in congenital imbecility and dementia præcox the ductless glands were all below the average weight. The paper was illustrated by a number of microphotographs.

The **PRESIDENT** gave a microscopical demonstration of the changes in the nervous system in hypothyroidism. He discussed the changes he had found present in the nervous system in six cases of the condition. These chromolytic changes he first observed ten years ago in a case of myxœdema which was under his care at Charing Cross Hospital, as reported to the International Medical Congress at Lisbon, in a communication entitled "Cerebral Lesions in Relation to Psychoses of Toxic Origin." Mr. Arthur Edmunds, working in his laboratory, had found similar changes in dogs from which the thyroid gland had been removed. The changes in question were not specific of hypothyroidism; this metabolic change in the cells had been found in other conditions also. In the Proceedings of the Society in 1913 (Vol. VI.) he gave an account of the microscopical investigation of the nervous system in three cases of spontaneous myxœdema. In the case of a woman whom Dr. Armstrong-Jones had sent for him to see there was anæmia, but the only signs of hypothyroidism present were slight dryness and harshness of skin, a malar flush, and slowness of speech. She showed marked confusion. She died shortly afterwards, and he (Dr. Mott) examined the thyroid gland and nervous system. As the changes seen in her had been since found also in three other asylum cases, the faults which had been described by Dr. Kojima might be regarded as established, seeing that these had now been found in six cases. The thyroid showed only a few remnants of glandular structure amid the lymphoid structure, and a large excess of fibrous tissue. The autonomic centres in the medulla were more affected than were the other cells, but all the cells of the central nervous system and spinal ganglia, especially the small viscero-vascular cells, exhibited some chromolytic change. The processes were but indistinctly seen, and the nucleus was excentric. He specially wished to show the changes in the cortex, so as to correlate the mental symptoms with the changes in the cortical cells. These he demonstrated by a series of slides. A section from the cardio-inhibitory centre in a typical case of myxœdema showed a pericellular chromatolysis in all the cells. Similar changes were seen in the glosso-pharyngeal nucleus and the psychomotor cortex; the cortical pyramidal cells had lost their position, and instead of lying in columns with the apical processes pointing upwards, they were twisted from side to side. A superficial layer of the cortex, stained with Victorian blue, showed a network of glial cells and a superficial felting in the cortex, owing to the extreme glial proliferation. A low-power slide showed that the columns of Meynert, formed by the pyramidal cells and their processes, were too indistinct to be recognised, their places being partly taken by nuclei of proliferated glial cells. In these cases there had been a change which led to the disappearance of the substance known as the Nissl substance, which probably occurred on account of an alteration of the osmotic conditions of the cells, allowing water to pass in and swell the cell. If, as was supposed, this basophile substance was the kinetoplasm, this change constituted a physical reason for the slowness of speech and cerebration which these cases manifested. The President also showed slides of ganglion cells in the living stage, as viewed with the dark ground microscope; an enormous number of highly refractile granules were seen in the cell. The little granules of fluid were enclosed by a thin membrane which stained blue, and this formed the Nissl granules when death occurred. This change could be watched. His view was that these granules formed an enormous oxygen surface, because if they were stained blue and placed in an atmosphere of nitrogen in a warm chamber the colour disappeared; but on letting oxygen in the colour returned. It would be important to be able to prove that the Nissl substance was the energy substance, for in hypothyroidism there was a definite lack of that substance, and it would account for the loss of mental capacity and of alertness of response observed in these patients.

Dr. **ARMSTRONG-JONES** exhibited a number of cases of Hypothyroidism, a condition due to loss of function of the thyroid gland. He said that though Schiff described cases of this condition in 1859, Gull in the "sixties," Ord in 1880, Kocher in 1883, and Sir George Savage over 30 years ago in Tuke's "Dictionary of Psychological Medicine," where the association with insanity was indicated, it was through the special interest of Dr. Mott that the question was now raised in its bearing on insanity or mental disease, for he made the relation of the ductless glands (thyroid, suprarenal, pituitary, ovaries, and testicles) the subject of his address last year. Sir Victor Horsley had demonstrated the effect of removal of the thyroid. A committee of the Clinical Society of London also studied the question, and it was known that the condition cachexia strumipriva, allied in all respects to myxœdema, was induced in animals by removal of the thyroid gland, and that this could be prevented by transplanting the thyroid of an animal into the peritoneum. Sir William Osler had stated that the thyroid became congested at puberty and during menstruation; also in women at the defloration period. Also, that the gland, or a lobe of it, became enlarged in conjunction with recent syphilis or secondary to infection. Baumann demonstrated that the nucleo-albumin of the gland contained a large percentage of iodine, and that it was present with protein matter within the vesicles of the thyroid; also that the gland manufactures some thyroantitoxin, and forms an internal secretion having the characteristics of an alkaloid. This substance had a profound physiological effect on the whole organism through the medium of the blood, for it acted as a hormone to other glands, while its absence was followed by physical and mental disturbance. On the physical side hyperthyroidism caused tremors, twitchings, tachycardia, headache, and prostration. Hypothyroidism caused an overgrowth of the subcutaneous tissue, the hands became unwieldy, the skin rough and harsh, and the hair disappeared or became sparse and wiry. On the mental side there was apathy, listlessness, and inactivity. Pawlow had shown how glandular secretions could be influenced by the emotions. In children absence of the thyroid produced sporadic cretinism and, possibly, idiocy of the Mongoloid type. In adults its absence eventuated in myxœdema. It was not by any means easy to recognise during life all cases of hypothyroidism, as some of the symptoms, such as tremor, seizures, and the mental reactions, were common to alcohol and general paralysis.

---

[2] THE LANCET, Feb. 13th, 1915, p. 324.

Dr. LENA BEACH exhibited and demonstrated a case of Disseminated Sclerosis.

Dr. SANO reported the result of his anatomical investigations regarding speech functions in a case in which there was a cyst of the left hemisphere, dating from birth or shortly afterwards. The lesion had destroyed the whole of the centrum ovale on the left side, but, notwithstanding that, the man had been able to earn his living as a clerk. The cortex remained, but practically the whole of the projection system was destroyed.

HARVEIAN SOCIETY OF LONDON.

Discussion on Cerebro-spinal Meningitis.

A MEETING of this society was held at the Stafford Rooms, Titchborne-street, W., on April 22nd, Dr. G. DE B. TURTLE, Vice-President, being in the chair.

In a few well-chosen words Dr. TURTLE expressed the great regret with which the news of the death of the President of the society, Dr. Edgar G. Bulleid, had been received, referring in terms of appreciation to the great services he had rendered to the society. A resolution embodying the latter sentiments was passed, and an expresion of sympathy was sent to the widow.

Dr. Turtle was then unanimously elected President for the remainder of the session.

Dr. F. E. BATTEN opened the discussion on Cerebro-spinal Meningitis with a paper which was published in THE LANCET last week (p. 964).

Dr. DAVID NABARRO gave a résumé of the history of the bacteriology of the disease from the discovery of the meningococcus by Weichselbaum in 1887 down to the latest work upon the subject during the recent epidemic. He then described the morphology and biology of the meningococcus, and gave an account of its occurrence in the human body. The changes in the chemistry and cytology of the cerebro-spinal fluid in meningococcal meningitis were described, and the alterations which are brought about by injections of serum. Finally, he showed a number of lantern slides of the meningococci in the cellular deposit of the cerebro-spinal fluid and in culture.

Dr. J. A. ARKWRIGHT dealt with the epidemiology of the disease. He divided the history of the epidemiology into three periods: (1) Before the discovery of the meningococcus; (2) the period commencing with the isolation and description of the diplococcus intracellularis in 1887; and (3) the period introduced by the discovery of the organism in the naso-pharynx of a patient and one carrier by Albrecht and Gohn in 1901. He then dealt with the large epidemics which have occurred since that date. The question of carriers was next considered. It had been shown by various observers that though the carriers were usually free from the meningococcus in two or three weeks a small percentage were still carriers after two or even seven months, and Mayer had related a case probably existing two years. Carriers might develop meningitis after two or three weeks, and no doubt all cases were carriers for a longer or shorter period. Subjects of meningitis must be looked upon as persons who in the course of a pharyngeal infection developed meningitis as a complication. The bacteriological examination of contacts was next referred to and the differential diagnosis between the meningococcus and other Gram-negative cocci found in the naso-pharynx discussed. Prophylaxis was then dealt with. The detention and isolation of carriers early in the epidemic whenever possible were advocated, with the avoidance of overcrowding and the breaking up of large bodies of troops into smaller units. The value of prophylactic vaccination was as yet uncertain. The morbidity, contagiousness, and seasonal variation were next discussed. The variation of the number of carriers among contacts in different epidemics was alluded to. Among 300 soldiers who were contacts Dr. Arkwright and his colleagues only found four carriers. In other epidemics as many as 23 and 32 per cent. had been found by various observers. In conclusion, he said that there were many points still requiring elucidation.

Dr. L. COLEBROOK spoke of the treatment of meningococcus infections by vaccines. He suggested that this procedure should not be considered as alternative to the intrathecal injection of serum, but rather as complementary to it. By the use of serum it was hoped to check the multiplication of meningococci in the cerebro-spinal fluid, and possibly to promote their destruction by phagocytosis, and it remained for the patient's own antibacterial defences to deal with the microbes which had established themselves in the meningeal and cortical tissues—the more serious factor in the infection. By the inoculation of vaccine into uninfected tissues it was sought to whip up these antibacterial defences to a maximal effort. Dr. Colebrook referred briefly to his experience of about a dozen cases—some of the "posterior basic," others of the epidemic type—of meningococcal meningitis, in which vaccine had been used. He had several times seen the temperature come down promptly and the patient's condition improve in a manner which strongly suggested that the inoculation of vaccine had exercised a favourable influence on the infection. But sometimes it seemed that very serious injury had been done to the central nervous system by the invasion of the cortex, blocking of the foramina, &c., in the days or weeks of the disease prior to the commencement of vaccine treatment, and in these cases, although the infection might be controlled, as evidenced by the temperature, the taking of food, and so on, yet full recovery was very slow or did not ultimately occur. It was, therefore, of great importance to exploit the vaccine very early in the disease, for choice on the second or third day. Probably nothing was to be hoped for in the fulminant cases which ran their course within 24 hours, as the patient's response to vaccine would not be affected within a few hours at least, possibly a day or two. It might even do harm to inoculate a patient so suddenly overwhelmed with his infection. In view of the marked difference to reaction towards immune sera displayed by meningococci of various origins, it would seem best to use an autogenous vaccine whenever possible, but during an epidemic it was certainly worth while to try the effect of a polyvalent stock vaccine. Such a vaccine had recently been prepared at St. Mary's Hospital from some 15 strains isolated in various parts of the country. In reference to dosage of the vaccine, Dr. Colebrook suggested that the foremost consideration was the avoidance of any congestive focal reaction, particularly in cases with marked cerebral symptoms. He had seen the best results with doses of from 2,000,000 to 5,000,000 cocci in young children and 7,500,000 to 20,000,000 in adults. Such small doses should be repeated every third or fourth day. Replying later to a question by Sir JOHN BROADBENT, he said he had recently used the stock vaccine above referred to for the prophylactic inoculation of persons exposed to the danger of meningococcal infection and of carriers. He had hoped that the vaccine might help to get rid of the microbe from the naso-pharynx of carriers, but this had not happened with any regularity. He had used doses up to 2,000,000,000 subcutaneously and 300,000,000 intravenously for these purposes. There was usually no general reaction except after the intravenous doses.

Mr. H. G. Armstrong related his experience of an epidemic, commencing on Jan. 24th last, of cases of an indefinite febrile nature characterised by œdematous throats, cough of a laryngeal type, little or no expectoration, and slow pulse. Ninety-four cases occurred by Feb. 8th. At this date relapses began to occur. On the 12th a woman exposed to the infection of these cases was taken ill with what was at first considered influenza. She died from meningitis on the 23rd. A baby, 1 year old, exposed to infection from this case on Feb. 19th sickened on the 23rd and died on the 24th from cerebro-spinal meningitis. On the 18th, among the cases of relapse an eruption of a roseolar type was noted, mostly confined to the abdomen, forearms, and legs. In one case the eruption was general and resembled measles, in another it resembled scarlet fever. Several cases had herpes labialis and other painful erythematous patches. With one exception all made a speedy recovery, but the first case of the series developed cerebro-spinal meningitis, confirmed bacteriologically. Another case occurred on March 5th and the patient died within 24 hours, meningococci being found in both blood and spinal fluid. All cases of relapse with rashes had vomiting of straw-coloured fluid.

Dr. H. Lyon Smith and Sir John Broadbent, the latter of whom discussed the mechanism of the infection, also spoke.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Localisation of Modern Projectiles with Reference to a Special Method of Surgical Technique in their Removal.

A meeting of this section was held on April 9th, Mr. H. Stokes being in the chair.

Dr. W. S. Haughton, in opening a discussion on the above subject, gave an account of the different methods of localisation in use, and described in detail the method which he recommended as the simplest and most exact. He then gave the surgical details he advocated in the removal of foreign bodies, and described fully a case he had recently under his care of a bullet lodged deep in the spinal muscles of the neck.

Mr. M. R. J. Hayes said that if Dr. Haughton had succeeded in spanning the gulf between the radiologist and the surgeon he was to be thanked, as in no department of their work was the gap so great between the radiologist and the surgeon as in the localisation of foreign bodies. He agreed with Dr. Haughton that the most accurate method of localisation was the Mackenzie Davidson method. It was more complicated than the methods usually employed, but he considered that the additional labour was fully repaid by the results. He considered Henderson's method, which was very expeditious and if properly carried out was fairly accurate, not at all as good as the Mackenzie Davidson. He suggested that in the localisation of bullets which were fairly large what was wanted was to get a fairly accurate method which was at the same time easy of employment, and he thought that with further experience of the triangular method it was quite probable that the results would be better than they had hitherto been. In looking for fairly large foreign bodies, if one could get within 2 or 3 millimetres there would be no difficulty in finding them, and it was only in the case of foreign bodies in the eye that one would be driven to the use of the more difficult method of Mackenzie Davidson. Mr. Hayes suggested that there were a great many foreign bodies which would be far better left alone, and he had seen cases in which the attempts at removal had done far greater damage than would have arisen had they not been interfered with. Referring to the interpretation of radiograms, he agreed with Dr. Haughton that no one was in as good a position to know the exact site in the limb of a foreign body as the radiographer. He suggested that even the expert radiographer, if given a perfect skiagram and asked to locate the foreign body, would experience as much difficulty as the surgeon who had not the experience. A point which should not be lost sight of in attempting to find a foreign body was the position which the limb was in at the time of localisation, and it should also be remembered that the approximation of depth was always open to error, as the substance being dealt with was subject to alteration by gravity and pressure. Another point of importance which should be attended to by surgeons was that when cutting down upon a foreign body it was very easy at the commencement of the incision to follow a line which one believed to be in the direction of the bullet, but one might go a little to one side, and by the time the object was reached, if it was deeply situated, he would be well to one side or the other.

Mr. W. I. de C. Wheeler said that a point which struck him was that if the bullet was localised and not found the whole fault lay with the surgeon, and this he agreed with to a certain extent.

Mr. P. E. Hayden agreed with Mr. Hayes that failures were often due to the deepening of the wound not being done quite in line where the incision was made. He suggested that a very valuable help in avoiding this mistake was first to mark the sites on the skin at either end of the wound. In deepening the wound it was advisable to look along these marks.

Mr. C. M. Benson also referred to the difficulty of cutting down straight upon the foreign body, and suggested that this difficulty was removed by Dr. Haughton's idea of putting down a long sterile probe, and he thought that if two of them were used one could be absolutely certain of going in the right direction without being dependent on the eye to correct any retraction on the wound.

Dr. Haughton, replying to the remarks, said he agreed with Mr. Hayes that in some cases very accurate methods of localisation were not required. He also admitted that if a bullet was lodged in a muscular pad it might safely be left there, but in his paper he assumed that the cases to be dealt with were those in which it would be considered desirable to operate. The influence of gravity in the localisation he had not lost sight of, and he considered it an important point which should be taken into account. He avoided suggesting any screening methods which involved length of time on account of the evil results of excessive exposure, and he would earnestly exhort everyone to keep away from screening as much as possible. He considered that the little gauge wire and the sterile needle demonstrated by him would be of the greatest assistance to the surgeon.

West London Medico-Chirurgical Society.—A meeting of this society was held at the West London Hospital on May 7th, Dr. S. D. Clippingdale being in the chair.—Dr. H. J. F. Simson read a paper entitled "Some Developments in the Management of Labour." He began by pointing out how often it happened among married women of every class of society that when they came to consult their medical attendant they dated the beginning of their ailment from the last confinement. Such a state of affairs went to prove that the methods generally practised left some room for improvement. With regard to the question of a painless labour, about which so much had been said lately in the lay as well as the professional papers, the results of using morphine and scopolamine to produce the so-called "twilight sleep" were not so free from objection as many wished the profession and the public to believe. It was not free from risk either to the mother or the child. There was little doubt that the use of chloroform increased the risk of post-partum hæmorrhage, and the after-effects were often so unpleasant that multiparæ frequently preferred to endure the pains of labour during their later confinements. However desirable it was to enable labour to take place without pain, the fact remained that it was not yet possible to do this in all cases without risk. The greatest source of danger from external help lay in the possibility of puerperal infection. It was quite true that the absolutely sure way of preventing avoidable infection was to depend on abdominal palpation for diagnosing the position of the fœtus, and if one waited until there was pressure on the pelvic floor before giving chloroform one could be more or less certain that the os was fully dilated. Before this stage of labour was reached, however, the patient often suffered a lot of pain. For instance, a slightly œdematous anterior lip coming down in front of the head often prolonged the last part of the first stage by half an hour or more besides causing much pain. How much better it was to push the anterior lip up between the pains; this would entail passing the finger into the vagina, of course. The point he wished to make was: if one can trust to one's precautions it does not matter, within reason, how often we examined in the last half hour, any more than if under proper conditions the hand is put frequently into the abdominal cavity during a laparotomy, but one must be able to trust implicitly in the precautions. With regard to the risk from post-partum hæmorrhage where means were taken to ensure painless delivery, either with chloroform or in the incomplete anæsthesia from scopolamine and morphine, the application of forceps at the end of half an hour's chloroform got over the difficulty if the chloroform was combined with the early administration of scopolamine and morphine, and a hypodermic injection of pituitrin shortly before the forceps were used.—Dr. Leonard Dobson considered Dr. Simson's paper so lucid and practical that there was little to add and nothing to criticise. With regard to the use of rubber gloves he had given them up as he found it practically impossible to keep them sterile during the progress of the confinement. He now relied on thorough washing and sterilising as for an operation and the use of a bowl of antiseptic solution into which the hands were frequently dipped. His experience of morphine and scopolamine had not been satisfactory and he had given up using it, especially on account of the effects on the child. He quite agreed as to the value of pituitrin given in the way Dr. Simson mentioned; the only drawback he had noticed was that occasionally the placenta was retained owing to the uterus contracting upon it instead of expelling it. With regard to the use of chloroform, he made it a rule never to give this unless the os was fully dilated and one could reasonably anticipate the birth of the head in about half an hour.—Dr. G. C. Crichton said that his experience taught him that the application of the forceps should not be too long delayed, whether the prolongation be due to fatigue or to a slightly contracted pelvis. As to antiseptic methods, great care and thought were needed in even ordinary simple cases; in the matter of cleanliness nothing was to be taken for granted.—Dr. Clippingdale gave some interesting details of historic confinements.—Dr. Vernon Monckton, Dr. S. R. Schofield, Dr. G. L. Turnbull, and Mr. W. P. Mallam also took part in the discussion.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 20th, Dr. A. Manknell being in the chair.—Dr. T. Jason Wood read a paper entitled "Some Remarks on Diagnosis in Abdominal Cases." These cases divided themselves broadly into two groups: (*a*) Those in which the symptoms were of sudden onset; and (*b*) those in which the symptoms were more moderate and of longer standing. In any case the chief things to decide were: 1. Was the patient's illness due to serious organic disease? 2. Was it a case in which operation was desirable or necessary, and when should operation be undertaken? Dr. Wood advised operation in all cases of serious abdominal injury if the pulse was good, as the probability was that some organ was ruptured. If the pulse was bad, the probabilities must be balanced and operation undertaken if possible. In civil practice all penetrating wounds should be operated on. In acute abdominal illness he laid stress on the fact that accurate diagnosis is well-nigh impossible. After enumerating the various conditions which may confront the surgeon when called upon to see an "acute abdomen," he pointed out that the first thing to decide was whether or not there was a perforation of a hollow viscus, as in these cases a few hours' delay meant death instead of recovery for the patient. He laid great stress on the fact that every case of severe abdominal pain is worthy of the closest examination from the very first. The cause of it is more likely to be serious than trivial. Until a diagnosis excluding certain things has been arrived at, purgatives on the one hand and morphia on the other should be avoided. Even though a perforation may have occurred no signs of collapse may be present.—The paper was discussed by Dr. W. Mitchell, Dr. D. Clow, Mr. G. H. Oliver, and Mr. J. Phillips, and Dr. Wood replied.—Mr. Oliver read a paper entitled "Some Remarks on Toxic Amblyopia." After mentioning the various drugs which have long been known to cause amblyopia, such as methyl and ethyl alcohol, lead, tobacco, male-fern, quinine, muscarine, iodoform, ergot, and many others, Mr. Oliver wished specially to draw attention to a new drug which had lately made its appearance in the treatment of pneumonia—namely, ethyl-hydrocuprein. He was called in consultation early in February to see a patient who had been very ill with pneumonia in the first week of January. Five-grain doses of ethyl-hydrocuprein were given every three hours. On the fourth day he had severe tinnitus and deafness, and on the fifth day he became suddenly blind, with semi-dilated and fixed pupils. In all he took 120 grains of the drug. He had bare perception of light, the retinal vessels were reduced to fine threads, and both discs were quite white and atrophic. Some slight improvement had taken place since.—Dr. J. C. Sykes introduced a discussion on the End-results of Gastro-enterostomy. He said that gastro-enterostomy had become one of the most fashionable and successful of modern operations, but unfortunately there were many failures, chiefly owing to faulty selection of cases. He severely condemned the surgeon who performed the operation in the absence of any trace of ulcer and comforted himself with the belief that it could drain the stomach and so relieve the suffering. It could not be too clearly emphasised that no good could come from gastro-enterostomy, ulcer though there be, if the pylorus was still patent and unobstructed. No food whatever would pass through an anastomotic opening, however large, so long as the outlet from the pylorus remained patent.—Mr. Phillips disagreed with Dr. Sykes's statement that no good could come from gastro-enterostomy if the pylorus was still patent, and quoted many cases where he had performed the operation with excellent results.—Dr. Mitchell said that X rays showed distinctly that food did pass through an anastomotic opening, even though the pylorus were patent.—Mr. Oliver, Dr. Wood, Dr. R. A. R. Lankester, and Dr. Manknell also took part in the discussion, and Dr. Sykes replied.

MEDICAL SOCIETY OF LONDON.—At the annual general meeting held on May 10th the following officers were elected:—President: Dr. William Pasteur. Vice-Presidents: Dr. David Lloyd Roberts, Sir St. Clair Thomson, Dr. Guthrie Neville Caley, and Mr. Walter H. H. Jessop. Treasurer: Dr. J. Mitchell Bruce. Librarian: Dr. Arthur Francis Voelcker. Honorary Secretaries: Sir John Broadbent and Mr. Hugh Lett. Honorary Secretary for Foreign Correspondence: Mr. Edmund Owen. Council: Mr. Donald Armour, Dr. Francis F. H. Bateman, Sir John Bland-Sutton, Dr. W. Ironside Bruce, Dr. Edmund Cautley, Mr. Edred M. Corner, Sir David Ferrier, Dr. H. Morley Fletcher, Dr. Herbert French, Mr. George E. Gask, Dr. John Gay, Dr. Bruce E. Goff, Mr. John D. Malcolm, Mr. Herbert S. Pendlebury, Dr. Guthrie Rankin, Dr. James H. Stowers, Mr. J. W. Thomson Walker, Dr. H. D. Waugh, Dr. W. H. Willcox, and Dr. Robert A. Young. After the business had been transacted a selection of the society's old and rare medical works were exhibited. Refreshments and smoking terminated the meeting. Owing to the absence of Sir William Osler on military service the annual oration and conversazione will not take place this year.

SMALL-POX AND VACCINATION IN BRISTOL.—At the last meeting of the Bristol health committee Dr. D. S. Davies, the medical officer of health, stated that the local outbreak of small-pox introduced from India was now practically at an end. Referring to vaccination, he remarked that it was difficult to get people re-vaccinated until they were face to face with small-pox, when they usually yielded without great demur. He added that he had recently had the gratification of vaccinating the originator of the antivaccination league in Bristol.

SANITARY INSPECTORS' EXAMINATION BOARD.—At the recent examination for qualifying sanitary inspectors under the provisions of the Public Health (London) Act, 1891, the examiners were Sir Arthur Whitelegge, chief inspector of factories and workshops (chairman); Dr. W. J. Howarth, medical officer of the City of London; Dr. Charles Porter, medical officer of health of St. Marylebone; Mr. O. Hall, medical officer of health of Plymouth; and Mr. R. Stephen Ayling, F.R.I.B.A. The examination included the inspection of artisans' dwellings and report thereon by the candidates, and the examination of specimens of meat and other foods provided by the Corporation from the City markets and specimens of fish provided by the Fishmongers' Company. Candidates were present from provincial towns as well as the London district, and 70 per cent. succeeded in passing the full examination.

Reviews and Notices of Books.

The Brain in Health and Disease.

By Joseph Shaw Bolton, M.D., D.Sc. Lond., F.R.C.P. Lond., Professor of Mental Diseases, University of Leeds; Medical Director, West Riding Asylum, Wakefield, &c. London: Edward Arnold. 1914. Pp. 479. Price 18*s*. net.

Those who have followed with interest and instruction Professor Shaw Bolton's researches on the correlation of cerebral structure and cerebral function and of mental symptomatology and cerebral pathology—as epitomised, for instance, in his recent Goulstonian lectures—will extend a ready welcome to this more ambitious volume, in which he deals with his systematic researches of some 18 years in a comprehensive fashion. In a brief but important preface he makes clear his point of view. After referring to the strides taken by biochemistry, bacteriology, and pathological psychology, and remarking that each of the methods of research based on these has been claimed by its advocates as the long-sought-for means by which the knowledge of psychology and of psychiatry would at last be advanced, he states that his volume is a contribution to the subject which is based on the old anatomo-clinical or clinico-pathological method, of which he truly remarks that it has been employed with success in the past in all the major investigations in the field of medicine.

The book is divided into two parts. The first deals with cerebral function in the normal brain: the minute histological features of the normal cortex are set forth in great detail and the accepted localisations of cerebral function are described and exemplified. The pathological changes in the cortex found in various mental diseases are given in similar detail, special attention being directed to those areas which are commonly affected. In this part of his subject Professor Shaw Bolton bases his findings on personal researches, which, for minuteness of investigation and breadth of interpretation, leave nothing to be desired. The second part of the book is concerned with cerebral function in mental disease. Taking the differentiation, which he has long advocated, of mental disease into "amentia"—i.e., subnormal cerebral function—and "dementia"—i.e., morbid cerebral function—the author proceeds to deal with the varieties of each, in every instance endeavouring to correlate their clinical features with their histo-pathology.

The author's main generalisation is based on a mass of clinical and pathological evidence which represents the work of many years, and is handled with great ability. He holds that the outer cell laminæ of the cortex subserve the associative, psychic, or educative functions of the cerebrum, in contradistinction to the inner layers, in which are localised the organic and instinctive functions. The subjects of amentia, in the sense above specified, are found, microscopically, to suffer from a more or less marked grade of deficient neuronic development, of subevolution of the cerebrum, while the subjects of dementia suffer from a more or less marked grade of true involution or dissolution. These changes are seen mainly in the cortex of the prefrontal region of the cerebrum. The existence of amentia does not preclude the onset of dementia. In arriving at these conclusions the author has made a specialty of the micrometric study of the cortex of the insane, and with unsurpassed patience has measured and investigated the histopathology of projection and association areas of the cortex in a very large number of brains from insane patients of every variety. His technique is described in detail, and well-reproduced illustrations render it easy for the reader to follow the author's argument and add materially to the value of the book.

It is clear that Professor Shaw Bolton has adduced evidence in favour of his main contentions which cannot be lightly set aside, nor can criticism be adequate unless it is based on the utilisation of similar material and on the prosecution of similar investigations. The alienist and the neurologist, indeed, the general physician, should be familiar with this monograph, in which the clinico-pathological method is shown to the greatest advantage and in which is embodied, as it were incidentally, a whole series of illuminating observations on the problems of cerebral function and cerebral localisation. At a time when indiscriminate resort to purely psychological methods of investigation might appear almost to be forcing a disruption of clinical phenomena in mental disease from any corresponding pathology, the solidly based researches here reported deserve the closest attention, and we anticipate for them a widespread recognition.

Flies in Relation to Disease: Bloodsucking Flies.

By E. Hindle, B.A., Ph.D. Cambridge: University Press. 1914. Pp. 398.

This is a companion volume to one recently reviewed in this column which dealt with the transference of disease by non-bloodsucking flies.

In the present volume the author details the present state of our knowledge concerning those flies which by their bite directly transfer parasites to the bodies of their victims and the nature of the parasites thus injected into human and other beings. The book, in fact, is a zoological handbook, but the author assumes a general knowledge of that science on the part of his readers. Any person thus prepared will obtain from the study of Dr. Hindle's guide a very good general acquaintance with the anatomy of the diptera, and also an insight into the systematic arrangement of those flies which form the subject of the treatise. Similarly, though to a less degree, the structure and life-histories of the parasites, protozoa and filariæ, are set before the student of this department of biology. The author, however, by no means neglects the utilitarian aspect of his subject.

Observing (in the preface) that "the fly's proboscis is more successful in retarding the progress of civilisation and the alleviation of human suffering than all the armaments of our most Christian Powers!" he reassures the less expert readers that as to yellow fever, "owing to the factors involved being relatively simple, it is literally possible within a few months to remove this most deadly disease from the list of human ailments." This and other diseases are entered into in the text with due regard to their history in the past and the symptoms available for their detection. Dr. Hindle points out the curious fact that so long ago as 1848 the origin of yellow fever was attributed to "some insect or mosquito." This, of course, was in the nature of a happy guess, for the real association between flies and the spread of disease is, as is well known, a matter of recent discovery. In the case of yellow fever, however, the discovery is very far from complete. Though the fly responsible has been tracked and is known to be Stegomyia fasciata, the parasite which it carries has not been hunted down. In the case of the, also tropical, disease dengue, the author gives us, what he does not in the case of yellow fever, two most informing maps; of these, one shows the range of the sickness and the other the distribution of the mosquito involved, which has been ascertained to be Culex fatigans. There is a very close correspondence between the two, which can be grasped at a glance.

This excellent volume shows us that while zoologists can justly boast of the utilitarian as well as philosophical importance of their studies, the medical profession have on their side given great stimulation to the investigations of the zoologists. The anatomy and systematic arrangement of various insects and protozoa are now becoming the best explored regions of the animal kingdom.

Castration and Ovariotomy.

By FREDERICK T. G. HOBDAY, F.R.C.V.S., F.R.S.E., Honorary Veterinary Surgeon to His Majesty the King; Examiner in Surgery and Obstetrics to the Royal College of Veterinary Surgeons, &c. London and Edinburgh: W. and A. K. Johnston. 1914. Pp. 162.

THIS is the second edition of a little book which has been out of print for some years, and that a second edition of a work on such a subject as "The Castration of Cryptorchid Horses and the Ovariotomy of Troublesome Mares" should be demanded proves that the tendency for "specialising" in animal surgery is moving with the times in the same way as has been the case in human practice. The new edition has been enlarged to include the castration of the domesticated and semi-domesticated animals, and the work of other specialists in this line has been freely quoted.

The first chapter deals with castration, and includes a clear account of the best and most usual methods of performing this operation in a large number of animals. The operations practised for scrotal hernia in the horse, dog, pig, and calf are next described, and then the author considers the interesting question of the castration of cryptorchid horses. The term "rig" or "ridgling" is commonly applied to horses with an undescended testicle. The origin of the term is uncertain, but one form of it—viz., "ridgil"—occurs in Dryden, who in his translation of Virgil's Pastorals, says:—

> And ware the Libyan ridgil's butting head.

Horses with this condition are notoriously vicious and uncertain animals, and their amorous tendencies often cause a great deal of trouble to their owners. Possibly it is this trait which explains the name "rig," since this word was employed by the old writers to denote a wanton or a strumpet. No doubt some male pseudo-hermaphrodites among horses are of this character, and in parts of the country the curious name of "Will-Gill" is applied to these animals. The derivation of this term also is a matter of curiosity. Can it be from will to wander, and gill or jill, a girl; denoting a similar conception of the characteristics of the animal to that implied by the name "rig." Most of the horses affected in this way are sterile, although potent, and the operation of castration is extremely successful in curing them of their "rig" propensities. As Mr. Hobday points out, to ensure success the strictest surgical cleanliness is as essential as in operations on the human subject.

Just as castration is a most useful operation in cryptorchid horses, so ovariotomy can often be practised with great success in the case of mares who suffer from a condition of troublesome, almost constant, œstrum. The failures are, as a rule, only in the case of old animals in whom kicking has become a habit, and if the operation is performed before the condition has existed for any length of time the results are excellent. The operation is performed by choice by the vaginal route, the posterior fornix being opened with a guarded knife, the opening enlarged with the fingers, the hand introduced into the abdominal cavity, and the ovaries removed by an écraseur. If the operation is done successfully there is practically no bleeding and the after recovery is very rapid. In one case alluded to by the author the mare was hunted on the sixth day after the operation and no ill-effects followed. In mares who have become a nuisance on account of indecent behaviour the author states that the operation almost always cures, and this opinion is based upon the results of more than 90 consecutive cases in which this operation has been performed.

Another interesting and useful operation described is the spaying of cows when they are nearing the age at which their dairy utility is diminishing. As a result the milk-supply is increased in quantity and enriched in quality, and the period of lactation is extended to an average of about 18 months. This procedure is practised to a very large extent in Switzerland, but for some reason or other an attempt made by the late Professor John Gamgee to introduce it into this country was not successful. It is interesting at the present time to recall the fact that the originator of the method of operating through the vagina in the cow is M. Charlier, of Rheims. Professor Flocard has recorded 5079 cases of spaying in cows, and in the last 3000 animals he has had no deaths and only 4 or 5 per cent. of accidents of secondary importance. An interesting final chapter on abnormalities of the sexual glands of man and horses is contributed by Sir John Bland-Sutton.

This brochure, as its author terms it, forms extremely interesting reading, and gives a very good and complete account of the two operations of which it mainly treats.

Animal Experimentation and Medical Progress.

By WILLIAM WILLIAMS KEEN, M.D., LL.D., Professor Emeritus of Surgery, Jefferson College, Philadelphia. With an introduction by CHARLES W. ELIOT, LL.D., President Emeritus of Harvard University. Boston and New York: Houghton Mifflin Company; London: Constable and Co. 1914. Pp. 312. Price 7*s.* 6*d.* net.

"THERE is not, and there never was on this earth, a work of human policy so well deserving of examination as the Roman Catholic Church." So, practically, begins one of the best known of Macaulay's essays. But there is another work of human policy which, although its life has been ephemeral compared to that of the Church, whether Western or Eastern, may take Macaulay's words to itself, especially when we remember who it was that said, "The Son of Man is not come to destroy men's lives but to save them." And that work is the great work of lessening or preventing disease and of rendering the most intricate operations of surgery possible and safe which scientific men of all nations have been carrying out for many years past, and especially within the last 50 years. That work is now undergoing the most stringent test possible on the battle fields of Europe, and nobly does it answer to the test. For the British part of the long battle line we have the report of Sir John French[1] as to the general health of the army, and among other things he says: "I would particularly comment upon the energy displayed by the Royal Army Medical Corps in the scientific efforts they have made to discover and check disease in its earliest stages by a system of experimental research, which I think has never before been so fully developed in the field."

Now practically the whole of modern surgery, the whole of preventive medicine, and the greater part of clinical medicine is rooted in and grounded upon researches made upon animals. These facts are, or should be, known to all medical men, though there are apparently some who are either ignorant of them or who do not believe them; but many a layman is naturally unacquainted with such facts, and to such we recommend Professor Keen's excellent book. It is a reprint of sundry papers and addresses, published or delivered from time to time between 1889 and 1913, and is divided into two main portions. The first comprises papers dealing with what has been accomplished by animal experimentation, the second includes those dealing with what Professor Keen calls misrepresentation on the part of objectors to "vivisection," using the word as the said objectors are wont to do, in its widest sense as signifying any kind of experiment upon a living animal. On the former portion it is unnecessary to enlarge, but in regard to the latter it is as well to insist on certain points. There is no one who will object to persons disliking vivisection or even as a matter of invincible ignorance denying that any advantages have accrued to humanity therefrom. The ignorant and the foolish have always existed, and will probably continue to exist. But what all honest men, whether they approve of vivisection or not, must reprobate, is the way in which the opponents of research try to bolster up their cause. The following examples of misrepresentation given by Professor Keen may serve as samples. One appears on p. vi., in which is quoted a letter written by Mrs. Henderson, Vice-President of the American Antivivisection Society, to the *Philadelphia Ledger* of Dec. 19th, 1913. In this letter she asserts, says Professor Keen, that "Dr. Crile's book ...... repeatedly describes experiments followed by the words 'no anæsthesia!'" Dr. Crile answered this charge by saying that in not a single instance do these words appear in his book ("Surgical Shock"). Professor Keen could not find them either, but he did find the following words: "In all cases the animals were anæsthetised." Mrs. Henderson, on being challenged both by Professor Keen and by the editor of *Harper's Magazine* to name the pages in question, did not reply, nor do we know that she has replied since this book was published. An even worse case is the misrepresentation of Dr. Wentworth, of Boston, of whom the antivivisectionists wrote in the *Journal of Zoophily* for April, 1910, that he experimented "upon between 40 and 50 little children in the Children's Hospital of that city, every one of whom died after the performance of his operation." The whole story is too long to quote, but shortly the facts are these. The date was 1895 when the operation of lumbar puncture was new. Thirty children had 45 punctures made. In 3 cases the puncture was made after death. In 15 of the 30 cases the puncture was made for diagnostic purposes, meningitis being suspected. In the other 15 cases the puncture was made for cytological research. Of the 27 living children who had the operation performed 14 died, not from the puncture, but from meningitis, or tubercle, or pneumonia.

We recommend, in conclusion, the persual of the series of papers at pp. 110 *et seq.;* these contain a correspondence with Mr. James M. Brown, President of the American Humane Association, which commenced on Oct. 4th, 1900. Professor Keen's polite and crushing rejoinder to Mr. Brown would have afforded keen joy to those past masters in the art of flattening out controversial opponents, the late Professors Huxley and Goldwin Smith.

LIBRARY TABLE.

Health for the Middle Aged. By SEYMOUR TAYLOR, M.D. Aberd., F.R.C.P. Lond. London: Methuen and Co. 1915. Price 1s. net.—In writing this excellent little book for laymen, Dr. Seymour Taylor has confined himself to useful generalities, excluding technical medical terms and giving advice as to the conduct of daily life that anybody should be able to understand and take. He who would live long should above all things be moderate in four indulgences—namely, eating, alcohol, tobacco (the cigarette habit is specially barred), and exercise. In addition Dr. Taylor recommends plenty of sleep, absence of worry, and the investment of cash in an annuity or insurance policy. The book may be warmly recommended to the middle aged, for whom it is written, though the advice will often reach them too late. For its perusal suggests the thought that the habits formed in youth are not readily altered in the second half of life. Much of the good advice it contains may be found in the old saw of the medical school at Salerno, dating, appropriately enough, from the Middle Ages:

> Si tibi deficiant medici, medici tibi fiant
> Haec tria; mens hilaris, requies, moderata diaeta.

An Introduction to School Hygiene. By W. B. DRUMMOND, M.B., C.M. Edin., F.R.C.P. Edin. With illustrations. London: Edward Arnold. 1915. Pp. 237. Price 3s. 6d.—This little work on school hygiene is written for teachers and students of education. Since the introduction of the medical inspector into the school teachers have shown a commendable interest in all those factors which directly influence the health of their pupils and indirectly their learning capacity. Although many works have been published on school hygiene most of them are too medical or too technical for the average assistant teacher in an elementary school. Dr. Drummond has successfully found the *via media* between the too scientific and the too popular. He explains in quite simple language how defects in the organs of special sense, the eye and the ear, may be discovered by an intelligent and observant teacher, and how unhygienic and insanitary conditions may detrimentally influence the physical health of school children and consequently their capacity for acquiring knowledge. A whole chapter, and a very useful one, is devoted to the care of the voice and the defects of speech. Professor Wyllie's classification, physiological alphabet, and methods are described sufficiently plainly to enable the teacher to discover in his pupils the causes of many speech defects and their mode of correction. We are glad to notice that the author warns his readers against forced breathing, which, he says, may lead to stiffness and rigidity of the chest walls; and in this connexion it might have been of equal service if a timely warning had been offered against attempts at making children breathe through the nose when the nasal air passages are too narrow to permit of adequate respiration by this route. Considerable attention is devoted to the subjects of heating, lighting, and ventilation, but the information afforded is highly practical and free from scientific technicalities. On school buildings some useful observations will be found, and a model plan on the Staffordshire type is commended to the notice of teachers as fulfilling at the least expense most of the admitted requirements. The central hall with its inherent faults and impediments to cross-ventilation is condemned, although the compactness which the system affords is admitted to facilitate mechanical ventilation—an advantage that the author cynically observes will appeal to those who regard this kind of ventilation as an end and not as a means. As a short, interesting, and up-to-date introduction to school hygiene we strongly commend Dr. Drummond's little book to the notice of educationists.

---

[1] The Times, April 15th.

Glaucoma: A Symposium Presented at a Meeting of the Chicago Ophthalmological Society, Nov. 17th, 1913. Edited by WILLIS O. NANCE, M.D., President of the Chicago Ophthalmological Society (1913), and WESLEY HAMILTON PECK, M.D., President of the Chicago Ophthalmological Society. Chicago: Chicago Medical Book Company. 1914. Pp. 150. Price 6*s*.—In this symposium on glaucoma the whole subject is reviewed from various standpoints by well-known American ophthalmologists, and Lieutenant-Colonel R. H. Elliot, I.M.S., the only Englishman contributing, deals with the operation of trephining which he has so ably advocated. Operations other than scleral trephining for the relief of glaucoma are described by Dr. Casey A. Wood. The etiology and classification of glaucoma are reviewed by Dr. Edward Jackson, the pathology by Dr. John E. Weeks, and treatment by non-surgical measures by Dr. George E. de Schweinitz. None of the papers is really exhaustive, but all are good and contain instructive material. The paper by Dr. de Schweinitz is particularly noteworthy for its completeness and sound sense. Much as all ophthalmologists appreciate the value of trephining, it is well to be reminded, as Dr. de Schweinitz reminds us, that "increased tension is not the whole story of glaucoma, and a filtering cicatrix is not the last word in surgical therapeutics, but there is much to learn."

Bibby's Book on Milk. Section II., The Law relating to the Sale of Milk. Fourth edition. 1914. Liverpool: J. Bibby and Sons. Pp. 256. Price 4*s*. net.—In addition to articles on the history of the law as affecting the trade of milk, with criticism of its administration and suggestions for its amendment, this volume will be found to contain a good deal of miscellaneous information, not always available in legal text-books, in the form of copious extracts from reported cases. These include not only those reported in the lawyer's sense—i.e., published as decisions of the higher courts in the accepted law reports—but cases in courts of summary jurisdiction, which may throw light upon the practical working of the law relating to adulteration and other topics, but which usually are not available for the purpose of reference. Explanatory notes on the Food and Drugs Acts, extracted, with acknowledgment, from Stone's Justices' Manual, Bell's Sale of Food and Drugs Acts, and Mr. Hedderwick's volume on the same subject, summarise in a convenient manner information capable of being of use to those whose duty it is to safeguard the food-supply of the public.

JOURNALS.

Journal of Anatomy and Physiology. Conducted by Sir WILLIAM TURNER, K.C.B., Professor ALEX. MACALISTER, Professor ARTHUR THOMSON, Professor ARTHUR KEITH, and Professor ARTHUR ROBINSON. Vol. XLIX. Third Series, Vol. X., Part III. April, 1915. London: Charles Griffin and Co. Annual subscription, 21*s*., post free.—Apparently there is no portion of the human body that can be exhausted as a subject for the researches even of gross anatomy. It certainly seems that it is impossible to come to an end of the anatomy of the femur. Within the last two years the femur has been the subject of a great many papers, and yet Dr. Thomas Walmsley in his two studies has managed to find plenty of new material. His first contribution deals with certain structural details of the neck of the femur, and the second with the neck of the femur as a static problem; and we are of opinion that both these contributions will prove the stimulus to further work. Both studies are of great interest and are permanent and solid contributions to the literature of the femur. We would remind the author that both H. Cloquet and J. Cloquet were surgeons and anatomists.—Another careful study is that by Dr. R. J. M'Connell on the Topographical and Applied Anatomy of the Gall-bladder and Bile-ducts, a paper the type of which we have rather missed from the journal of late. The illustrations are particularly good, and in them one can detect what one may express with admiration as the influence of the Belfast school.—Anomalies are dealt with in the remaining papers. Dr. James C. Brash describes in great detail a vertebral column with six and a half cervical and 13 true thoracic vertebræ, with associated anomalies of the cervical spinal cord and nerves. The column was obtained from a male subject aged 61, and it is an extremely anomalous one of a type not uncommon in malformed fœtuses. Dr. Brash has made a very exhaustive study of the spinal column, the spinal cord and nerves, and he concludes (we believe quite rightly) that the "bone condition is secondary to the nerve anomaly."—Two cases of Cervical Ribs are described by Miss M. F. Lucas (here designated as "Mr."). The paper is one which we hope will be imitated, since the arrangement of all the vertebral elements and the constituents of the limb plexuses are recorded in detail. The anomalies are found not infrequently in the dissecting room, and it is only by records such as these that the study of the subject is likely to be advanced. Too often the associated parts, which alone may help in an understanding of the condition, are dissected away or disregarded when note is made of the anomaly. The paper is well illustrated.—Miss Lucas also contributes a paper on an Anomalous Arrangement of the Vagi. At first sight the case is a remarkable one, for the usual spiral arrangement of the vagi on the œsophagus is exactly reversed, the right nerve lying in front of, and the left behind a normally situated œsophagus and stomach. The author, however, concludes that only an exaggeration of a not infrequent type of resolution of the plexus gulæ is present.—Dr. Douglas G. Reid continues his studies of the disposition of the peritoneum with a contribution on Appendices Epiploicæ and Pericolic Membranes.—Under Anatomical Notes Professor E. Fawcett describes and illustrates two rare and interesting cases. The first is that of an internal mammary artery arising from the thyroid axis; the second is an instance of the rare condition of the external semilunar cartilage forming a complete circular disc covering the external tibial facet. There is surely a misprint in the statement that "Bruce Clarke saw three such cases in one *limb*."

The Philippine Journal of Tropical Medicine, Vol. IX., No. 6.—The first article of this number is by Dr. E. H. Ruediger, who writes upon the subject of the germicidal power of glycerine on various micro-organisms under differing conditions. From his experiments he concludes that glycerine has a distinct though feeble germicidal action, and that it seems to be a selective poison for the bacillus of plague, the spirillum of cholera, and the bacillus of diphtheria. In 50 per cent. of glycerine in physiological salt solution all the non-sporing organisms died in less than four days. Dr. Ruediger makes no reference to the fact that for nearly 20 years the bactericidal action of glycerine has been used to remove the extraneous organisms from vaccine lymph in England and other European countries.—Dr. Otto Schöbl has been carrying out researches on the vitality of cholera vibrios in Manila waters. He has found that these vibrios remained longer alive in less polluted waters than in those more highly contaminated, and that the organisms disappeared earliest from distilled water, remaining most numerous in the sea water.—The morphology of the adults of the filaria found in the Philippine Islands is described by Dr. Ernest Linwood Walker, who expresses the opinion that the Philippine filaria is identical with F. bancrofti.—Dr. Honoria Acosta Sison, of the Department of Obstetrics in the University of the Philippines, contributes an article on pelvimetry and cephalometry among the Filipinas. From her observations she finds that the Filipino pelvis is smaller than that of the American or European, and this may to some extent be explained by the smaller stature of the Filipino race. The transverse diameters of the Filipino pelvis, except the transverse diameter of the pelvic outlet, are smaller than those of the European or American. The relative enlargement of the transverse diameter of the pelvic outlet may be explained by the habitual squatting position that the Filipinas assume, and by the fact that the carrying of the child astride the hips of the mother or nurse may also affect the child in the transverse diameter of its pelvic outlet. The head of the newly born infant is proportionate with the Filipino pelvis.—Dr. R. B. Gibson supplies a note on the physiological action of the proteoses, and the same writer in conjunction with Dr. Isabelo Concepcion furnishes a paper on the lymphagogic action of the Philippine mango, Mangifera indica (Linnæus).—Dr. Concepcion also contributes some observations on mango rash. It appears that transient eruptions of an erythematous type occur in the natives of the Philippines during the hot season, and are attributed popularly to the eating of mangos. Dr. Concepcion extended the observations to ascertain if the fruit had any influence in this respect upon infants through the mother's milk. Four newly confined mothers in the obstetrical ward of the Philippine General Hospital were selected for experiment and were given six mangos daily with their meals. In all the cases except one rashes were produced on both mother and child. It is believed that the babies are more susceptible than the mothers.—An interesting instance of milk poisoning due to a type of staphylococcus albus occurring in the udder of a healthy cow is described by Dr. M. A. Barber. The symptoms produced resembled those of so-called ptomaine poisoning. The cases occurred from time to time on a certain farm, and extended over a period of about four years. The particular cow whose udder was discovered to be infected had been imported from Australia. The fresh milk was harmless, but when it had stood for some hours at a room temperature a toxin was developed in sufficient quantity to give rise to acute gastric disturbance. Culturally the toxin-producing staphylococcus differed little from a non-toxin producing strain, except that the former produced acid in mannite and maltose litmus agars. This number completes Vol. IX.

ERRATUM.—In the review of Sir Edward Schäfer's "Introduction to the Study of the Endocrine Glands and Internal Secretions," published last week on p. 970 of THE LANCET, Sir Edward Schäfer's newly coined word "autacoid" was spelt "antacoid" by a printer's error. We take this opportunity to correct the mistake; the word "autacoid," derived from the Greek *ἀυτός*, self, and *ἄκος*, a medicinal agent or remedy, was applied to the specific hormones and chalones of internal secretions in order to draw attention to the way in which their action resembles the action of drugs, such as the vegetable alkaloids.

THE late Mrs. T. Aitken has left £10,000 each to the Ramsbottom Cottage Hospital and the Aitken Sanatorium for Consumption at Holcombe, near Bury.

AN ANALYSIS OF THE NATURAL MINERAL WATERS OF VERGÉZE, FRANCE (SOURCE PERRIER).

INASMUCH as Perrier water is supplied to this country in very large quantities, and is rapidly increasing in popularity, an independent examination of it from a hygienic point of view may be held to be desirable in the public interest. We have been asked to give a detailed opinion of the suitability of Perrier water for table purposes based upon a consideration of the conditions under which the water is bottled and sent to the consumer, and upon the results of our own chemical and bacteriological examinations of the water.

We have received samples direct from the springs and have made our own purchase of samples upon the market, all of which have been submitted to chemical and bacteriological examination. The samples examined included two taken from the springs, the first not being under pressure, and the second having been aerated with the natural gas which escapes in large quantities from the springs.

The results of the bacteriological and chemical examinations of these samples were compared with those obtained with the samples representing those purchased by the public, and this comparison appears in the figures given below. In addition, we have made certain inquiries as to the situation of the springs and as to the methods of bottling the water, which, of course, needs to be carefully carried out in order to preserve the water in a state of purity desirable for drinking purposes.

Source Perrier owes its name, it is interesting in passing to remark, to a well-known medical man, Dr. Louis Perrier, of Nimes, a town situated some nine miles away from the springs at Vergéze, Gard. There is abundant evidence to show that the springs were known to the Romans, but not until recent times was it realised that "the boiling springs"—"les bouillens," as they are locally called—might furnish a plentiful supply of natural aerated water for table purposes. Chiefly through Dr. Perrier's energy the plant and machinery for bottling in bulk was installed near the springs, and this natural sparkling table water soon enjoyed a considerable patronage not only in France but in this country also.

The complete purity of both the natural water and carbonic acid gas demands very careful watching in the bottling process in order to avoid the slightest departure from a high standard, and the natural circumstances well assist the efforts of the proprietors. The springs are situated in the midst of fields and vineyards far from human habitations. They rise in the Cevennes mountains, visible at a distance of some miles, and thence flowing underground through sandstone, clay, and chalk, emerge to the surface at Vergéze, in the Midi, and some twenty miles from the sea coast in the direction of Montpellier. Of the springs available the one chosen for bottling purposes is the least mineralised. Special precautions are taken to bottle the water under the cleanliest conditions possible. To this end the bottles are subjected to a thorough washing process effected by machinery, and all pipes conveying gas and water and the aerating plant itself are kept scrupulously clean. If strict attention was not practised in any one of these directions the bottled water would not pass the requirements of both chemical and bacteriological standards of purity, in spite of the purity of the springs themselves.

Chemical Composition of Perrier Water.

According to an analysis made in THE LANCET Laboratory, samples of the water taken directly from the source, both still and sparkling, and samples procured on the market, show the following composition in regard to mineral ingredients, the results being given in grains per gallon :—

TABLE I.—*Chemical Composition.*

	Still from source.	Sparkling from source.	Market sample.
Calcium carbonate	26·04	28·00	29·40
,, sulphate	3·22	3·22	3·22
Magnesium carbonate	0·63	0·42	0·42
Sodium chloride	2·60	2·60	2·00
Silica	1·68	1·12	1·12
Total mineral matters ...	34·17	35·36	36·16

The water of Source Perrier thus belongs to the group of natural springs classed as "indifferent" or simple "acidulous" waters. It contains no active medicinal constituent. In a table water in constant use the presence of such may be undesirable. Even considering the total quantity of salts present, it is clear that the mineralisation is very moderate, and the chief constituent is carbonate of calcium dissolved in carbonic acid gas. The total salts amount to an average of 35 grains per gallon, or a little over 4 grains per pint, of which about three-fourths is carbonate of calcium. This salt in solution, of course, gives the water some antacid properties and, no doubt, adds to its palatability. A small quantity of sulphate of calcium is present also, confirming the statement as to the flow of the water through calcareous bearings, which are well known to furnish the purest water for potable purposes. Sodium chloride occurs only to the extent of 2 grains or so to the gallon, a quantity which can have very little importance from a therapeutic or palatable point of view. The analyses of the various samples obtained establish the identification of the water procured in the open market with the waters directly from the source, and further show that it is remarkably constant in composition.

Organic Purity of Perrier Water.

The same samples were next examined for organic purity by chemical analysis, and for this purpose the estimation of the free ammonia, albuminoid ammonia, nitrogen in nitrates, and oxygen absorbed was decided upon.

The following were the results given in parts per 100,000 :—

TABLE II.—*Organic Purity.*

	Still from source.	Sparkling from source.	Market sample.
Free ammonia	0·0006	Trace	Trace.
Albuminoid ammonia ...	0·0006	Trace	0·0007
Nitrogen in nitrates	0·4300	0·4100	0·4000
Oxygen absorbed	0·0280	0·0200	0·0400

A sample of the water from the spring and a sample also procured on the market were submitted to bacteriological analysis.

The sample taken direct from the spring without any special precautions gave the following results :—

Growth from 1/10 c.c.	Colonies per 1 c.c.
In gelatin at 22° C.	2680
In agar at 37° C.	810

There was no evidence of the presence of bacillus coli when operating on 200 c.c., 100 c.c., 10 c.c., 1 c.c., and 0·1 c.c. respectively, and the organisms present are of no importance pathologically. The complete absence of coliform organisms or streptococci is remarkable, and shows the water is well guarded from contamination. The sample procured on the open market gave still more striking results. It contained neither bacteria in 1 c.c. nor bacillus coli in 100 c.c., and the water is thus seen to be sterile.

In Table II. are recorded the results of examination in regard to organic purity based upon the estimation of free ammonia, albuminoid ammonia, nitrogen in nitrates, and the oxygen absorbed from a weak permanganate solution. The figures obtained demonstrate an unusual degree of organic purity which, in fact, surpasses that of most of the public water supplies. This speaks well for the precautions taken to guard the source from contamination and for the cleanliness of the bottling processes. Perrier is thus an exceptionally pure water.

Bacterial Purity of the Water.

Consistently with the high degree of organic purity revealed by chemical examination the bacteriological results negatived contamination. Samples of Perrier water procured on the market were, in fact, shown to be sterile, no ordinary water bacteria being present, and a search for bacillus coli failed to find this organism, even when 100 c.c. of the water was examined. In the sample obtained direct from the spring some harmless water bacteria were found, but again no bacillus coli. There are few natural waters which would not show bacteria present in 1 c.c., the deep well water showing the least, and the river or surface water the most number. It seems clear that Perrier water is derived from a very deep source, which accounts for its bacterial purity, and this purity is maintained up to the time it reaches the consumer, the risks entailed by collecting and bottling being removed by scrupulous care in the processes. These results incidentally point also to the bacteriological purity of the natural carbonic acid gas and of the cleanliness observed in the aeration process.

The Natural Carbonic Acid Gas of the Perrier Springs.

The carbonic acid gas was carefully collected from a bottle of Perrier water and examined. It proved to contain 99·65 per cent. of pure carbonic acid gas, the residue, 0·35 per cent., consisting of about equal volumes of nitrogen and oxygen.

Conclusions.

These results of analyses show that Perrier water can stand the most exacting ordeal required by chemical and bacteriological investigation in regard to questions of purity. It possesses no objectionable mineral salts, is organically pure, and is perfectly free from harmful bacterial life. The samples obtained upon the market were, in fact, sterile. Such findings afford a strong recommendation in regard to any potable water, and in a water pleasantly aerated with the natural carbonic acid gas of the springs the result is particularly satisfactory. The care taken to preserve the water in its pure state on its way from the springs to the consumer has clearly been complete. The advantages of natural carbonic acid gas in table waters are still a matter of controversy, some maintaining that the chemically prepared gas is less easily assimilable. There is one important difference which is noticeable when natural gas is used, and that is, it gives a softer and pleasanter taste to the water and renders it more palatable and digestible. For some reason artificial gas gives a sharper, more strongly acid taste to table water than does the natural gas, and this may well prove to be a dietetic disadvantage. Some medical men in France attach great importance to the use of natural gas for aeration purposes and attribute to it a more favourable action on the gastric processes, but it is generally agreed that the moderate use of aerated beverages promotes digestion and stimulates the motor activity of the stomach. There is evidence that they help digestion also by a mechanical process, the bubbling up of the gas through the stomach contents facilitating their disintegration. The natural effervescing waters appear also to influence osmotic processes to a greater degree than artificial mineral waters, and thus increase the powers of absorption and promote diuretic action.

It may be added that Perrier water has been systematically and periodically examined by Dr. Wilson Hake, lecturer on chemistry and toxicology in the Westminster Hospital Medical School, since the water was placed upon the market in 1904 to the present time. The many results he has thus obtained in his controls show no appreciable deviation from his first figures, and our recent analyses confirm his work in all significant particulars.

THE PEREIRA MEDAL.—At the May meeting of the council of the Pharmaceutical Society the Pereira medal was adjudicated to Miss Dora F. White. This medal—which is generally regarded as the blue ribbon of pharmacy—was struck in 1861 in memory of Jonathan Pereira, the great authority on materia medica, and has been awarded annually ever since. This is the second time it has been won by a woman pharmacist. The Pharmaceutical Society's silver medal has been won by Mr. A. J. Somes and the bronze medal by Mr. R. W. Bowles.

THE LANCET.

LONDON: SATURDAY, MAY 15, 1915.

The Scarcity of Medical Men: The Proposal of the Pharmaceutical Society.

SOON after mobilisation it was realised that the wave of enthusiasm for active service was likely to affect the number of medical students presenting themselves for examination. From all medical schools came accounts, not only of diminished entries of new students, but of the serious depletion in the ranks of students who had already reached their third and fourth year of medical studies. The desire to be on active service in defence of the realm had led many to enlist, and it was therefore realised that, unless some means of adjusting the balance could be devised, there was likely to be a serious shortage in the supply of medical men for the future needs of the nation. This difficulty, which is entirely disconnected with the immediate needs of the Army Medical Service, was early recognised by the President of the General Medical Council, and on his representation an order was issued releasing from the responsibilities of enlistment which they had incurred all medical students in their third or fourth year, so that they might be able to resume the normal course of their work and fit themselves for qualification at the earliest possible date. It was realised that these men, who had already gone through several years of training in the preliminary subjects, would be far more useful to the nation in their medical capacity than they could possibly be as simple units in the army. As these young men become qualified they will probably join the Royal Army Medical Corps if the war still goes on. In this service the younger men are likely to be more pliant and more ready cheerfully to carry out orders in face of difficulties than older men, who might naturally resent having their instructions given to them by officers who, though superior in rank, must be younger in years. But while the younger men obtain in this way an enviable pride of place, the older men, whom circumstances have reserved for home service, are meeting the needs of the civilian population with alacrity, and are displaying a willing readiness to adapt themselves to war conditions. In many cases work that has hitherto been done by younger members of the profession must be distributed amongst those who had thought that their period of drudgery was over. The rush for the Army Medical Service has naturally involved in difficulties many public institutions. The conditions of resident appointments have been relaxed, with the result that many appointments, both as residents and as pharmacists, have been filled by people of far more than the usual age, or by women. But these changes may be regarded as temporary. It is to be anticipated that, when the war is over, those who have been serving abroad, and who desire to return to their former sphere of work, will find it easy to do so.

In common fairness to those medical men who have temporarily given up their work in this country, it is essential that no steps should be taken which would place them at a disadvantage when the needs of the army no longer call for their services. There has been displayed a spirit of *camaraderie* by which medical men have undertaken to carry on the work of absent neighbours as though they were partners, and where such arrangements have been made general practitioners will, in all probability, speedily be able to resume their practices. There remains, however, the scarcity of medical men owing to the absorption of the youth of the nation on active service—we do not know what the measure of this scarcity may be, but we are sure it has been exaggerated. Letters have been published in the *Pharmaceutical Journal* holding out that the present affords an opportunity for pharmacists to enter the medical profession. It has been urged that special facilities should be granted to those who have already qualified as pharmacists, and the proposal seems to have culminated in active measures being taken by the Pharmaceutical Society. The writers of the letters believe that many pharmacists would enter the medical profession if the present regulations were temporarily altered, and it is suggested that, if the examinations they have already passed were allowed to rank at full value, the numbers of men in the medical profession might speedily be increased. It is stated by one contributor to the correspondence that this would benefit both the medical profession, in which there is such a scarcity of men, and the pharmaceutical profession, which is suffering in some districts from an unmistakable plethora. It is not pointed out in what way members of the medical profession are to be benefited by finding their numbers largely increased when they return from active service. Perhaps the idea is that with greater competition there may be less work for each individual, but this may not produce a living wage without strenuous effort and much anxiety.

The concessions suggested for pharmacists are: (1) Exemption from the Preliminary Examination and from matriculation; (2) exemption from chemistry and botany in the First Professional Examination; and (3) exemption from materia medica and pharmacy in the Second Professional Examination. While the movement was confined to correspondence it was right to take no notice of it, even though it was urged that chemists' associations throughout the country should get up a petition to the Pharmaceutical Society asking the Council to approach the medical or Government authorities with a view to modifying the curriculum. The question, however, has now been crystallised by a letter to the Registrar of the General Medical Council, officially addressed to him by the direction of the President of the Pharmaceutical Society. This letter definitely asks that qualified pharmacists may be excused the Preliminary Medical Examination and such parts of the qualifying examination as are included in the subjects which pharmacists have to pass in order to qualify under the Pharmacy Acts. It would seem to be somewhat unlikely that much sympathy will be shown by the General Medical Council towards this relaxation of medical examinations, while it is highly improbable that any of the aspirants for medical qualifications could be qualified in time to take active service in the army during the war. If they are unable to help the nation in this way, it would seem that the only benefit resulting from any compliance with their requests would be a benefit to the individual pharmacists concerned; while, on the other hand, medical men now serving at the front might, within a few years, find the ranks of the medical profession inconveniently crowded. We have no desire to oppose the entrance of pharmacists to our ranks. There are already numerous instances of medical men who have attained professional eminence after having steadily gone through the full course of study of both departments; but this should not lead to any hasty alteration of a curriculum which has been gradually and carefully evolved with such great benefit to scientific medicine. While we are sure that the General Medical Council will not be influenced by the spirit of antagonism recently displayed towards it by some of the members of the Pharmaceutical Society, we trust that the reply given will be firm, judicious, and unmistakable in its purport.

Chlorine Poisoning.

There remains little doubt that the gas employed by the Germans against our soldiers in the trenches was chlorine. The evidence of the newspapers and the descriptions of the sufferings of the "gassed" pointed, as we said in our issue of May 1st, to one conclusion—namely, that chlorine was the disastrous agent used. Chlorine is cheap, can be preserved in liquid form, or generated from bleaching-powder cubes, and as it is nearly two and a half times as heavy as the air it is capable of manipulation. Investigations have now been conducted on the bodies of the victims, and the observations made coincide closely with those recorded from time to time in industrial cases of chlorine poisoning. The following case, given in Dr. Witthaus's "Manual of Toxicology," sets out, for example, a train of symptoms which are typical and which show a remarkable accordance with the symptoms displayed by the poisoned victims at Ypres. The patient described by Dr. Witthaus had inhaled a small quantity of the pure gas. He immediately experienced an inclination to cough, and complained of dyspnœa and a stabbing pain in the chest, which continued through the evening and became still worse the next morning when the dyspnœa was intense, and coughing was almost uninterrupted. The patient was greatly excited and spoke only with difficulty. The heart impulse was not perceptible, but the heart sounds were clear. Sibilant râles were heard, particularly to the right and above. The face was cyanosed. The dyspnœa now increased markedly, every respiratory muscle was called into play, the movements of respiration were short, there was cyanosis, and the pulse was very frequent and small. The patient slept occasionally for half an hour, woke struggling, the pulse became imperceptible, there were râles in the throat, and he died about 48 hours after the inhalation. There need be no question as to whether the Germans appreciated the horrible fate to which they were condemning the victims of chlorine inhalation—the tortures of the death were common knowledge.

Chlorine and its compounds appear to result in the formation of hydrochloric acid in contact with the moist mucous membranes, and the symptoms are generally a sensation of suffocation, difficulty of breathing, and lacrymation. The gas severely attacks the respiratory organs, bronchial catarrh, inflammation of the lungs with frothy blood-stained expectoration supervening. Apart from the method of pouring chlorine gas into the air intended to travel in the direction of the opposing forces, the Germans have apparently contrived to despatch the gas by means of shells, and one officer's experience of the bursting of these outrageous missiles is of interest as confirming the effects recorded in cases of industrial poisoning. On the bursting of these shells, he states, a green gas was developed, and before he and his comrades had a chance of moving they were inhaling the poisonous gas and a moment later they were struggling terribly for breath. Two of the men died before his eyes, which afforded a horrible sight, "for they had turned quite blue." He escaped with others owing, he thought, to the fact that they had stuffed their handkerchiefs into their mouths. They felt at the time, however, that suffocation was inevitable, and afterwards they experienced the discomforts which follow an attack of bronchitis in its most virulent form. He had no doubt at all, in his own mind, that the gas in the shells and the curtain of "creeping gas" were of the same nature. It is generally stated that chlorine gas in the proportion of as little as 0·04 to 0·06 per 1000 taken into the lungs is dangerous to life, and the effects, for all intents and purposes, are much the same as those of hydrochloric acid gas. But of course the formation of hydrochloric acid due to chlorine acting upon moist membranes means that it is present in the nascent form, in which form it is far more active—that is to say destructive.

The question of replying to this new and revolting form of warfare by similar application to the forces and resources of chemistry has been freely discussed. Chlorine is certainly as available for the Allies as for Germany, but the method is full of uncertainties, particularly when the letting loose of the gas into air currents calculated to reach the enemy is relied upon. Already it has been reported that the German calculations sometimes failed and that the attacking party received the gas by return currents. The method at any rate can only have relatively local effects, and its success has been much due to the surprise and terror which it momentarily caused. If the Allies decide to retaliate, as they have every right to do, they may be depended to improve on the infamous example set them. This country possesses enormous resources in regard to the manufacture of chlorine and its compounds. This is seen in the fact that while England produces about 200,000 tons of bleaching powder (the chief reservoir of chlorine output), France produces 60,000 tons, and Germany 100,000 tons. But at the present time ingenuity is being exercised only for defensive purposes. The distribution of chlorine in explosive shells may offer a serious problem unless effective means are found to ward off attacks by means of "anti-chlor" saturated respirators. Of the numerous "anti-chlors" available hyposulphite of soda is the best; the respirators found on captured German soldiers proved to be moistened with hyposulphite, confirming the conclusion that the gas used was chlorine. Next to hyposulphite common carbonate of soda is most efficacious. Failing these the respirator moistened with water would undoubtedly serve to reduce the severity of the attack. The Germans have probably employed liquid chlorine, of which they make large quantities in steel cylinders for industrial purposes. It is used for displacing bromine from the bromide liquors of the Stassfurt mines, and for the production of chloracetic acid, which is essential in the synthetic preparations of artificial indigo. The use of chlorine gas as an offensive weapon is new; its employment as a defensive weapon in the sterilisation of water for drinking purposes has for some time been recognised as effective. Civilised nations will agree, in the name of humanity, that its powers to destroy should be confined to low organisms. It may be suggested that just as war is war, so chemistry is chemistry, and that the use of one disastrous chemical agent is no more morally wrong than the use of another. Yet we must all feel that there is a vast difference between the skill of arms and the skill of the poisoner.

UNIVERSITY OF SHEFFIELD.—The Council, at its last meeting, appointed Mr. J. Sholto C. Douglas, M.A., D.M., B.Ch. Oxon., M.Sc. Birm., to the John Hunter chair of pathology, in succession to Professor H. R. Dean. Dr. Douglas is at present lecturer on pathology in the University of Manchester.

Annotations.

"Ne quid nimis."

THE SINKING OF THE "LUSITANIA": FATE OF MADAME DEPAGE.

THE sinking of the *Lusitania* is universally accepted as the crowning infamy in the German conduct of the war up to the date of its occurrence. The crime has been received with a chorus of horror throughout the world. True, when analysed, the deed is no baser than the murder of unfortunate fishermen in the North Sea, than the use of virulent gases in the trenches, or than the deliberate assassination of wounded prisoners—all of which proceedings we learn from authentic reports have marked the conduct of the war by the Germans during the recent weeks. Yet the cynicism of an action which condemned in a moment helpless women and children in crowds to a terrible death has impressed civilisation more than any other of the horrors which have followed upon the frequent breaches of international convention during the war. But the impression has not been that which presumably the Germans expected; disgust and resolute anger have been aroused, not shuddering fear.

To many of the medical profession the tragic fate of the *Lusitania* has a particular sadness, because one of the ill-starred passengers was Madame Depage, of Brussels. The deepest feelings of sympathy will be extended to Professor Depage on the tragic death of his wife. Madame Depage was on her way back from a tour in the United States to obtain funds for wounded Belgians in the Depage Hospital at La Panne. The generous mission was devotedly undertaken at great personal sacrifice, and now that it has ended in death a sense of personal grief will be experienced by the many friends in England whom she had so often welcomed at her house in the Avenue Louise, Brussels. The members of the Société Internationale de Chirurgie will, we are sure, not quickly forget her graciousness as a hostess, her wonderful power of organisation, her gaiety, her great linguistic powers, and the tact which enabled her to harmonise the clashing interests of a polyglot assembly. Last year she accompanied Professor Depage to the United States as the wife of the President of the Société Internationale de Chirurgie; and no better suppliant with the American people on behalf of Belgium could have been found. Bravely she left her husband and her children out of love of her stricken nation, and she has died in her country's cause.

THE SPIRIT DUTIES.

THE drastic proposals of the Chancellor of the Exchequer in regard to levying additional duties on wines and spirits have been withdrawn, and the suggestion we made in our columns three weeks ago has been adopted in principle. This was that the sale of immature spirits should be stopped by a system of compulsory bonding. Time is to be given to the industry to find the accommodation necessary for storage. Spirits up to two years will be compulsorily bonded, and a surtax is suggested to be levied on all spirits taken out of bond between two and three years of age. After that time it may be presumed that no surtax will be charged. The wine duties are not to be raised. There is to be a State control of all licensed houses in munition areas, and for this purpose a central board has been created composed of representatives of the Admiralty, War Office, and Home Office. On the whole a wise compromise has been reached and the proposals promise to offer a satisfactory settlement. They should remove, also, all anxiety as to the spirit used for medicinal purposes being further taxed.

NOTABLE REDUCTION OF TYPHOID FEVER IN ITALY.

It is only of late years that Italy has begun to apply large measures of sanitation to her whole united population. To many of us, accustomed to the better hygienic environment of our own country, residence in Italy has always caused anxiety, especially in regard to the possibility of contracting typhoid fever, and in some places this anxiety has been justified. But recently Italy has been very literally setting her house in order, and the risks of typhoid fever have much abated. We are just now more concerned for the possible fighting strength of the Italian army than for the security of the rare tourists of our own nationality who may be in Italy, but on both accounts it is good to learn of the general improvement in public health indicated by the decline in frequency of typhoid fever. The fighting strength of an army is naturally enhanced if it is recruited from healthy material. When the troops come from towns and villages where typhoid epidemics are frequent there is a greater danger that the army itself will be infected. This is often left out of calculation, the health of those with the colours being considered as though it can be independent of the conditions where the levies are raised. In Italy financial facilities for public health works, such as water-supply and drainage, have been greatly accelerated by the Public Health Acts of July 13th, 1905, and June 25th, 1911. It is especially in respect to small and poor districts that the State guarantees the interest on the money borrowed for sanitary purposes. Thus from July, 1905, to July, 1911, no less than 337 districts or communes received State aid for their water-supply works. During the same period 763 communes obtained financial aid for other public health undertakings, such as the building of isolation hospitals, improved drainage, &c. The result has been specially noticeable in regard to the prevalence of typhoid fever. Professor Santoliquido is responsible for the following figures. The cases of typhoid fever notified in 1888 amounted to 59,631, and there were 23,869 deaths; but in 1912 the number of cases was reduced to 30,558 and deaths to 7743. This means that whereas in 1888 there were 800 deaths from typhoid fever out of every million inhabitants, the proportion per million was only 221 in 1912. Of course, it may be said that these were exceptional years, and to a certain extent this is true, because they represent the highest and the lowest figure. Nevertheless, the reduction, while showing certain fluctuations, has been persistent. Thus the fall was gradual from 1880 to 1894, when the proportion of deaths per million of the population was only 439; but it rose again the following two years to 498, then to 520. In 1897 it was 491, and the year following 545. After that the figure never again attained to 500; and after the year 1900 it was always below 400. Finally, after the year 1905 the proportion of deaths from typhoid fever has always been below 300 per 1,000,000 inhabitants. We have therefore good reason to hope that the prevalence of typhoid fever has been definitely reduced by about two-thirds. This is no mean achievement, and the Italian authorities are to be congratulated.

UNUSUAL SYMPTOMS DUE TO GALL-STONES.

In another column we publish an interesting note on a case of gall-stones described by Dr. A. R. Neligan. The usual symptomatology of cholelithiasis is generally recognised, such as paroxysmal pain, vomiting, collapse, jaundice, and the presence of gall-stones in the motions, to which may be added the occurrence of ague-like attacks. During an attack of biliary colic the contents of the stomach are first vomited, and bile may also be present, but it is only in very rare instances that a calculus is vomited. In Dr. Neligan's case, however, a number of faceted gall-stones were found (about 30) in the vomit. We have been unable to find a similar record. In addition, the patient suffered from intestinal obstruction; an operation was recommended but refused, and after the administration of enemata she passed some flatus, liquid fæces, and a hard mass which subsequently proved to be a gall-stone. Unfortunately it was broken up before Dr. Neligan saw it, but apparently it must have been roughly round in shape and 3 centimetres in diameter, and must have weighed about 16 grammes. Mechanical obstruction of the intestines by a gall-stone is also uncommon, but many cases have been reported. Morestin[1] was able to refer to as many as 242 cases. Dr. H. D. Rolleston[2] states that the relative frequency of this cause to other causes of intestinal obstruction has been variously estimated at from 1 to 13 to 1 to 45. The occurrence of two unusual symptoms in the same patient—viz., the vomit of many gall-stones and the obstruction of the bowel by one such stone—is certainly remarkable, making the record of the case exceptionally interesting.

RADIOLOGICAL STUDIES OF THE LARGE INTESTINE.

Dr. A. E. Barclay, whose work on the alimentary tract is well known, contributes some interesting observations to the symposium on intestinal stasis in the current number of the *British Journal of Surgery*. Constipation is due less, he considers, to Lane's intestinal kinks than to an absence of what he terms *points d'appui*, from which, as fixed points, the mass movements of the fæces can be urged forward. These *points d'appui* appear to be variable in their site—they are never seen in the cæcum itself; more commonly such a point is found in the neighbourhood of the hepatic flexure. Under the X rays the mass is found to be pushed forward from the fixed point. Failure of such fixed points leads to inability of the large intestine mechanically to propel forwards, in the abrupt occasional and brief manner now recognised as typical, the fæcal mass. The "cess-pool," or loaded cæcum, under this view must be regarded less as the cause than the effect of such inefficient propelling action. This organ, in fact, is suggested to be little concerned in the propulsive action; it is often found to contain bismuth for a long time subsequent to its administration; it is not cleared out so effectively as are other parts within the sphere of the massed movements. Possibly the cæcum has a separate mechanism for mixing the contents and feeding them into the ascending colon preparatory to the occurrence of the mass movement. The significance of incompetence of the ileocæcal valve, a condition which Dr. Barclay confirms in his own observations in relation to chronic constipation, is not touched upon here. Not all cases of constipation are due to those motor disturbances of the large intestine thus described. Whilst stagnation of fæces in these cases is met with in the cæcum, the larger class of cases of constipation are due to stagnation in the rectum, a condition termed by Hertz "dyschezia." This is, however, a fault of defæcation rather than a true constipation. Dealing with the X ray findings in cases of neoplasm of the large intestine, the opaque enema is recommended in preference to oral administration. By the latter method it is only when the growth is very far advanced that definite banking up of the shadow behind the growth appears; generally, too, the head of the shadow seldom reaches the obstruction itself, suggesting hypertonicity of the colon above the site.

THE INEBRIATES ACT IN 1913.

IN submitting his report for 1913, with regard to institutions certified or licensed under the Inebriates Acts, 1879 to 1900, Dr. R. Welsh Branthwaite explains that owing to the pressure of other work both before and after the war he has been unable to incorporate observations on the medical aspects of inebriety in continuation of remarks made in a previous report. The report is therefore confined to the usual statistics relating to inmates of inebriate reformatories and retreats. As the total number of persons treated in these institutions has not been large many of the tables do not refer only to 1913, the year specially dealt with, but contain corresponding figures for each year since 1899, when the Act of 1898 came into force. Many of these are of interest, but attention may be specially called to one of them, because at the present time two topics upon which it has a more or less direct bearing are arresting public attention. It will be found that during the period included in the report, 1899 to 1913, there were in all 586 persons committed to certified inebriate reformatories for offences dealt with under Section 1 of the Act of 1898—that is to say from assizes and sessions. The nature of these offences is specified in the report, and it will be found that comparatively few involved conduct of the kind commonly regarded as seriously criminal in character. Only 47 persons in all were convicted of larceny, stealing and receiving, and 44 of attempted suicide, 13 of assault, and 7 of malicious wounding. In this connexion it is necessary, perhaps, to suggest that a very large number of serious offences due to inebriety are not so looked upon in the courts, but are punished in the usual way by imprisonment, without attempt at reformatory treatment. The one offence, however, which appears to be specially selected to be dealt with under the section mentioned is that of unlawfully neglecting children in a manner likely to cause them unnecessary suffering. Out of the 586 committals to inebriate reformatories referred to 459 were for offences of this kind, and as only 57 were men it will be seen that drunken mothers who neglect their children constitute a very large proportion of the persons sought to be reformed under Section 1. The "drink question" has been made prominent recently by delay alleged to be caused by intemperance in the production of munitions of war, and the figures cited above show a particular aspect of the effect likely to be produced by inebriety upon the rearing of a healthy generation of children, to compensate for the ghastly destruction of human life which the war is causing, and for the diminished birth-rate which may be expected in future years.

INJURIES OF THE PERIPHERAL NERVES.

INJURIES to the peripheral nerves are extremely common in warfare, and at the same time they form a class of case in which early and expert treatment is essential if the best results are to be obtained. At its meeting of March 4th the Société de Neurologie of Paris passed a resolution, which was forwarded to the French Minister of War, pointing out the extreme desirability of avoiding delay in transporting those with nerve injuries, and injuries of the nervous system generally, to the special neurological hospitals of Paris and elsewhere, since successful treatment depends on the care and minuteness with which the preliminary neurological investigation of such cases is prosecuted. The society points out how frequently the special hospitals are asked to take cases of traumatic neuritis in which, as the result of delay, fibro-tendinous retractions, sub-ankyloses, and other complications have supervened, which often prove rebellious to treatment. From a later number of the *Presse Médicale* we learn that improvement has taken place and that special neurological services have been established in connexion with various of the army hospitals. Similar utilisation of the expert neurological opinion of this country should be organised to its fullest extent, to obviate unsatisfactory results in cases treated originally, owing to stress of time and other circumstances, in an incomplete fashion. The French medical journals have contained a number of useful contributions to the study and treatment of traumatic lesions of the peripheral nerves. Among these may be mentioned a paper by M. Temoin, read before the Société de Chirurgie, emphasising the necessity of a complete motor, sensory, and electrical examination in all cases of peripheral nerve injury, to facilitate early and successful surgical intervention. M. Claude has given to the Académie de Médecine the results of 100 cases of peripheral nerve lesions operated on, and in the *Presse Médicale* of March 4th, with M. Vigouroux and M. Dumas, he records the results in a further series of 100 cases. All of these were examined by neurologists clinically and electrically before operation, and after operation they were given suitable secondary treatment. In a series of 56 cases there were 7 of complete section of a nerve trunk with separation of the ends, in 12 the nerve was cut across but the ends were together, in a fibrous development, in 21 the section was incomplete, 3 showed induration without section, and in 13 the nerve was compressed by perineural sclerosis. Apart from the complete sections, where improvement is a question of time mainly, in no fewer than 87 per cent. the result of surgical interference was amelioration of symptoms. In another series of 46 cases, improvement was obtained in 74 per cent. The paper contains useful hints for the surgeon. Another communication of interest appears in the *Presse Médicale* of March 18th from the service of Professor Pierre Marie at the Salpêtrière. Professor Marie gives a full description of an unusual variety of traumatic lesion of the median nerve, in which the symptoms are mainly sensory, the motor symptoms being slight. Instead of holding his hand in the characteristic position of median palsy, the patient keeps his fingers extended, sometimes the terminal phalanges are hyperextended, the thumb is in slight opposition. There is a fine tremor of the three radial fingers, and marked trophic and vaso-motor changes in the median distribution are always observable. The hand is warmer than its fellow, but, above all, it is "*atrocement douloureuse*." The maximum pain is in the pulp of the affected fingers and their nails; whatever be the site of the lesion in the nerve trunk this is the distribution of the pain. Dry heat always aggravates the condition, hence the patients cover their hand in cold, wet dressings, and keep renewing them themselves. So insignificant a stimulus as a cough increases the pain at once, and in three cases it was noted that grasping, with the sound hand, a warm object induced an exacerbation of the pain on the affected side. A yawn, a sneeze, even simple emotions such as seeing a fellow patient slip on a polished floor, a sudden noise, music, looking at a touching or an amusing picture, are all mentioned by Professor Marie as aggravating the neuralgia. Objective sensory changes are confined mainly to the tactile form. There is also a slight wasting of the muscles concerned, but, as already observed, never a pronounced paralysis. The pathological condition is probably one of traumatic ascending neuritis of the nerve, and operative treatment has not, in Professor Marie's experience, been very satisfactory. He makes the interesting observation that the musculo-spiral, ulnar, and median seem to vary somewhat in their reaction to injury; in the case of the musculo-spiral, the chief symptoms are paralysis, and there is little sensory change; in the case of the ulnar, with a traumatic main-en-griffe, there are few, if any, trophic and vaso-motor changes; while with the median the motor defects are secondary and, in some cases at least, pain and vaso-motor phenomena are extremely pronounced.

RUPTURE OF THE EXTENSOR LONGUS POLLICIS.

Dr. J. Ramsay Hunt has recorded in a recent issue of the *Journal of the American Medical Association* a case of a very rare injury—rupture of the tendon of the extensor longus pollicis. The patient was a tailor, aged 31 years, who worked from 10 to 12 hours daily, much of the time sewing with a coarse, heavy needle. He also used an iron for pressing clothes. On Oct. 25th, 1914, after a day's work, he inserted his right hand into his trousers pocket in search of some object, twisting the hand about as one does in trying to explore angles and recesses. He was seized with severe pain over the posterior surface of the wrist on the radial side and over the back of the first metacarpal bone. On removing his hand he could not extend the distal phalanx of the thumb, though he could easily flex it. For several days there was great pain over the dorsal surface of the wrist and first metacarpal bone, and for a fortnight this region was tender and showed some swelling. On examination on Dec. 1st there was paralysis of the extensor longus pollicis. The patient could strongly flex the distal phalanx of the thumb, but had not the least power of extension. In contrast there was fair power to extend the proximal phalanx and first metacarpal bone. When the tendons of the thumb were rendered prominent by strong extension the normal prominence of the extensor longus pollicis was absent. When the finger was drawn along the course of the long extensor there could be felt just below the posterior annular ligament a small movable rounded slightly tender swelling. This corresponded to the distal end of the ruptured tendon. The proximal end was not palpable. Electrical examination failed to elicit any response in the extensor longus pollicis, while all the other muscles reacted normally. The sensibility of the hand was normal. Suture of the tendon was recommended but declined. Normal tendons are so strong that rupture is almost impossible. In the case of severe strains either the muscle tears or the periosteal insertion of the tendon gives way, often carrying a fragment of bone. For a tendon to rupture it must have been previously weakened by disease. While rupture of the extensor longus pollicis is very rare in medical literature generally it has been well known to German military surgeons for a long time. In the medical reports of the Prussian army from 1870 to 1904 von Wurthenau collected 62 cases, all in drummers. The condition is the result of chronic tenosynovitis induced by a peculiar method of holding and using the left drumstick, which causes mechanical irritation of the tendon as it emerges from its compartment in the posterior annular ligament of the wrist. In time changes take place in the tendon and its sheath and eventually rupture occurs, either during a paroxysm of drumming or more rarely spontaneously. It is said that the affection occurs usually in beginners and exclusively on the left side. Microscopic examination of the severed tendons has shown hyaline swelling and necrosis and separation of the tendon fibres. Dr. Hunt thinks that in the case of the tailor there must have been similar changes in the tendon. It is curious that no warning pain seems to have been observed in any of the cases. But though rupture may occur painlessly, more frequently a piercing pain is felt over the back of the wrist, often shooting up the forearm. The tendon may be swollen and tender and the distal portion is often felt below the annular ligament as a tender movable nodule. Isolated instances of the lesion have been recorded in a compositor, a wood-carver, a farmer, and in waiters. As to treatment, if there is no evidence of union after a brief period of fixation, suture should be performed.

THE Croonian lectures will be delivered at the Royal College of Physicians of London on June 17th, 22nd, 24th, and 29th, at 5 P.M., by Surgeon-General Sir David Bruce, C.B., F.R.S., A.M.S. The subject will be Trypanosomes causing Disease in Man and Domestic Animals in Central Africa.

THE Progress of Public Health in Egypt is the subject which Dr. F. M. Sandwith has chosen for his course of four Gresham lectures to be delivered at the Gresham College, Basinghall-street, E.C., on May 18th, 19th, 20th, and 21st, at 6 P.M. The lectures will have a topical bearing.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Colloidal Gold in the Treatment of Infected Wounds.

M. Cunéo and M. Polland have been using colloidal gold in a whole series of infected traumatisms in which the phenomena of infection persisted in spite of the usual surgical measures. The gold was injected intravenously, intramuscularly, or hypodermically in the peripheral zone of the infected region. The clearest and most valuable results have been obtained in large wounds of limbs with infection by anaerobic microbes. In these cases a marked fall of temperature ensues, together with considerable diminution in the number and quality of pulsations and a return towards normal of the arterial pressure. Local modifications may also be observed in the wound; a diminution of the fœtid odour and secretion and attenuation of the œdema. These latter phenomena are even more influenced by local injections of colloidal gold. In penetrating wounds of the abdomen medically treated the authors have used this remedy as a preventive measure. In pyogenous infections the results of injections of colloidal gold have been less clear, perhaps because the authors have been led to employ them more in cases of infection of the serous membranes, where a local reaction sufficient to stop the processes of suppuration was not to be expected. The intravascular injections are followed by violent reaction; a severe rigor may last for 40 minutes. Sometimes the countenance becomes slightly cyanosed, the temperature rises, and the pulse is quickened. An abundant perspiration sets in later and may last sometimes several hours. When given intramuscularly colloidal gold gives rise to no reaction. It may be injected by this route up to 50 c.c. at a single time and several days in succession. Used thus the gold has a mode of action milder but also slower than that by the intravascular route. These injections may be also made by means of a long needle around the limits of the infected tissue, avoiding the vessels so as not to provoke by the entrance of some drops of the liquid directly into the blood the violent reaction of an intravenous injection. Intravenous injection is definitely indicated only where rapid effect is sought. In individuals with lowered tension recourse had better be had, at first at any rate, to the intramuscular route. Injections around the wound are especially indicated when a local action is desired.

Conservative versus *Radical Operations in the Surgery of the Limbs.*

M. Mauclaire has reported to the Société de Chirurgie on the work of Dr. Lapointe, who between Oct. 26th and Feb. 7th was at the front on medical duty, ten miles from the firing line. Here he saw more than 4000 wounded pass through his ambulance, and close on 800 operations were done, nearly all by himself. Out of this number, 547 presented fractures, crushings, and lacerations (*arrachements*) of the limbs. In the upper limb, out of 317 wounded 145 that were not operated on gave 9 deaths; out of 172 operated on, 104 by conservative operations gave 34 deaths, 68 by radical operations 11 deaths, or a total of 54 deaths. In the lower limb, out of 228 wounded, 90 not operated on gave 11 deaths; out of 138 operated on, 75 conservative operations gave 34 deaths, while 63 mutilating operations gave 28 deaths, or a total of 73 deaths. In the upper limb among the radical operations performed there were 68, with 11 deaths, or a mortality of 16 per cent. Three disarticulations of the wrist, 5 amputations of the forearm, 2 disarticulations of the elbow, all primary, had no deaths. Out of 42 amputations of the arm there were 6 deaths, of which 2 out of 33 primary amputations and 4 out of 9 secondary, 16 disarticulations of the shoulder gave 5 deaths, of which 2 out of 12 primary disarticulations and 3 out of 4 secondary disarticulations. Total, 4 deaths out of 55 primary radical operations, and 7 deaths out of 13 secondary. In the lower limb 65 mutilations out of 63 wounded, with 28 deaths, mortality 43 per cent. Three economic operations on the foot gave 3 cures; 21 amputations of the leg gave 5 deaths, of which 3 were in 17 primary and 2 in 4 secondary amputations; 40 amputations of the thigh gave 22 deaths (or 55 per cent.), of which 12 occurred in 25 primary and 10 in 15 secondary amputations. One primary disarticulation of the hip was followed by death. Nearly all the amputations were done by the circular method. For the disarticulation of the shoulder and for some high amputations of the arm and the leg, M. Lapointe employed "racket" amputation. He left the greater part of the stumps uncovered, because most of the wounds at the time of arrival at the ambulance were very seriously infected. For the sterilisation of instruments and gloves M. Lapointe employs sodium borate. The site of operation and the dressings have been treated in the same method up to the day when M. Lapointe was able to procure trioxymethylene and to prepare dry dressings instead. He has used oxygenated water, permanganate of potash, formol solution, 5 per 1000, and tincture of iodine.

Death of Dr. Thoinot.

Dr. Thoinot, professor of legal medicine at the Faculté de Médecine, and a member of the Académie de Médecine, has died very suddenly. In 1906 he succeeded his teacher, Brouardel, in the professorial chair. He was physician to the Hôpital Laennec, and from the beginning of the war médecin principal at the Val-de-Grâce and head of the service of contagious diseases. His writings are of importance, while as an expert he was highly esteemed in the judicial world, and his medico-legal work had gained for him an international reputation.

May 8th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

An Association of "Medical Advisers."

A NUMBER of the "medical advisers" and "certifiers" of the Irish Insurance Commission met in Dublin last week to form an organisation in defence of their interests. Having elected officers and a committee, they passed a resolution declaring their wish to assist in a settlement of the certification question, provided their own interests were safeguarded. It is generally thought that the present system of certification is about to be abandoned.

The Medical Profession and the War.

A committee has been appointed by the medical profession in Belfast (*a*) to make arrangements for looking after the practices of those who may become whole-time medical officers under the R.A.M.C., and (*b*) to form a list of practitioners willing to serve as whole-time officers for a short period.—At a meeting of the board of management of the Benn Ulster Eye, Ear, and Throat Hospital, held in Belfast on May 6th, it was decided to allow Dr. I. A. Davidson and

Dr. W. A. Anderson leave of absence for one year, they having offered their services to the War Office, and to keep their positions open for them. As a result the out-patient department will be open only three days a week.

LUNACY IN EGYPT.

THE FINAL REPORT FOR THE YEAR 1914.

RECENTLY we reviewed the delayed reports of 1912 and 1913[1] dealing with lunacy in Egypt, and now we have the final report of 1914 before us. As in Dr. J. Warnock's previous reports, we get a most complete history of the work carried on. And this has been done under trying conditions, as, owing to the death of Dr. Pearson, deputy superintendent, the administration has been short-handed. There is again complaint made that there is not sufficient accommodation for the patients, so that many have to be discharged before they are really mentally stable; hence relapses are frequent, and criminal acts are done by the unstable convalescents. In the main building at Abbassia the recent and acute cases are received, while at Khanka the more calm and chronic cases are occupied in agriculture. The report is for English readers chiefly interesting from the special causes of insanity, and for the medico-legal aspect of the partly cured patients.

Pellagra is a great cause of insanity; in fact, is given as the chief cause. Of 700 admissions, 132 were suffering from pellagrous insanity, 94 from hashish, and 40 from alcohol. General paralysis provided 41 cases. A very interesting table is the one showing the offences and forms of insanity of the 54 male accused persons, and the forms of insanity of the 21 male convicted prisoners admitted in 1914. Of the 54, 12 were suffering from pellagrous insanity, and 8 from that due to hashish. Of the 75 in whom there was a history of crime, 10 were pellagrous, and 6 of the insane from hashish were convicted of murder or murderous assaults. Every form of crime is represented by the pellagrous insane, but violence is the most common. Thirty-eight deaths were due to pellagra, but others suffering from tuberculosis had pellagra as well.

Nearly 6 per cent. of the male admissions were suffering from general paralysis, and 25 of the 125 deaths of male patients were due to the same disease. There was a slight decrease in the number of patients suffering from hashish insanity. Considering the prejudice against post-mortem examinations, it is interesting to find that 56 were performed. Dysentery was, as usual, represented, but was only responsible for nine deaths.

A pathological laboratory has been started, and as a result a special ward for observation and treatment of ankylostomiasis was opened. One hundred and ten patients were recently examined, and 29 proved to be infected; these were treated with thymol. No patient succeeded in committing suicide. A good many accidents occurred, due to violence in the overcrowded wards.

The report of Dr. H. W. Dudgeon for the Khanka Asylum is brief, but points to the steady development of the subsidiary asylum. It is also the model for a working asylum which is carried out and developing under rather trying conditions.

The Lunacy Department now being a branch of the Ministry of the Interior, and having an official head in Dr. Warnock, time and money alone are required to make the work very satisfactory as well as instructive.

---

[1] THE LANCET, Jan. 30th, 1915, p. 243.

SERVICE MEDICAL OFFICERS AND THE INCOME-TAX.

THERE are no doubt many medical men on war service who from one cause or another have not taken up the question of their income-tax for the past year and are not acquainted with their rights in regard to any tax that may have been paid in excess of their true liability. The service medical officer's position in regard to the income-tax is, moreover, of interest to those whose liability, though not affected for the year 1914–15, will be affected for the current year owing to the interference with their general practice. Before dealing with the matter it may be remarked that an officer who is in doubt as to the manner in which the tax that he has paid has been arrived at can obtain full particulars on application to the Surveyor of Taxes in regard to the private practice, and to the Assessor at the War Office or Admiralty in regard to official pay and allowances.

Claims for Adjustment.

The tax charged on pay and allowances is, of course, deducted by the paymaster, but unless the recipient has taken steps to ensure allowance of any relief due to him the tax will have been deducted at the full rate. The importance of taking measures to obtain any adjustment that may be due will be realised from the fact that in the case of earned incomes it is only where the total income from all sources exceeded £2500 that the full rate of 1*s*. 8*d*. for the past year was payable; on smaller incomes there was relief of 8*d*. in the £ where the total income was not more than £1000, 6*d*. where not more than £1500, 4*d*. where not more than £2000, and 1⅓*d*. where not more than £2500. In regard to this type of relief it must be observed that it is now too late to make any claim unless the officer filled in a statement of total income from all sources before Sept. 30th last, either by way of a specific claim to the "earned income" rate or in the ordinary course in making his professional return for the year 1914–15. The possibility to be guarded against is that, while relief has been allowed on the professional assessment, the reduction in the rate has not been extended to the War Office or Admiralty pay. Forms were issued to enable officers to make claims or to declare the address from which they had already claimed, and in cases where these were duly completed there is little likelihood of overcharge under this head; but it is not too late to obtain relief where an officer, having duly made his statement of total income from all sources locally, did not notify the War Office or Admiralty. The original statement will, of course, have proved inaccurate in the light of subsequent events, but it operates as a notification of claim, and an amended statement may now be put in for the purpose of obtaining repayment of any overcharge.

In this connexion there arises the question of the amount to be regarded as income from the practice for the year 1914–15 by those who for part of the year were engaged on war service. This matter was dealt with by the second Finance Act of last year. The assessment on the profits of the practice was originally made on a figure intended to represent the average profits of the three preceding years, but a special provision enacts that where a person has been serving as a member of the military or naval forces, or in any work abroad of the British Red Cross Society, St. John Ambulance Association, or any other body with similar objects, the assessment shall be reduced to the amount of the actual profits of the year and repayment of duty made where necessary. To secure this adjustment it will be necessary to submit to the Surveyor of Taxes an account of the receipts and expenses of the practice for the year 1914–15, prepared on the lines indicated in THE LANCET of April 24th, p. 878, and from that official may also be obtained the form necessary for any other repayment that may be due. In cases where the practitioner usually makes up his accounts to Dec. 31st and not to March 31st, it will be well to make an adjustment in order that full effect may be given to any falling off of receipts after Dec. 31st. This may be done by substituting the receipts in the first quarter of 1915 for those in the first quarter of 1914, and adding to the expenses of the year 1914 a sum representing the extra expense incurred by the employment of a locum-tenent for the first quarter of 1915. If it be not convenient to an officer to go fully into the matter at the moment, he should write to the surveyor notifying his desire for any adjustment that may be due to him, to be claimed when circumstances permit. There will be many cases in which the profits of the practice for the year, with the addition of the pay, have amounted to a sum so much less than the figure originally returned for assessment, that the total income from all sources, then shown as over one of the "earned income" limits, say £1000, has fallen below that limit, with the result that a new rate of duty will apply.

In determining the amount to be regarded as income from army pay, it is not necessary to take into account the field allowances, ration money, or servants' allowances; these seem to be regarded as not subject to income-tax, presumably on the ground that they are intended to defray expenses occasioned purely by the exigencies of military life. No corresponding relief appears, however, to be allowed when a uniform rate of pay is fixed to cover such allowances. It will usually be found the most convenient course to inquire of the assessor precisely what amount has been treated as subject to income-tax for the year ended April 5th, 1915, as suggested above.

Other Forms of Relief.

There are other descriptions of relief in respect of which repayment may be claimed by those to whom they have not already been allowed—that is to say, the allowance for life assurance premiums, the abatements of £160, £150, £120, and £70 on total incomes not exceeding £400, £500, £600, and £700, the deduction of £20 for each child under 16 years of age on April 6th, 1914, allowed where the total income does not exceed £500, and the "small incomes" relief, amounting for the past year to 4*d.* in the £ on incomes not exceeding £300 and $1\frac{1}{3}$*d.* in the £ on incomes not exceeding £500. The last-mentioned form of relief does not apply to income on which the "earned income" rate has been charged. In all these cases it is possible to claim repayment at any time within the next three years, but the preparation of the claim will involve the least trouble now, when the necessary figures and papers are readily available. The time-limit of three years does not apply to applications for adjustment on account of a falling-off of professional profits or non-allowance of the "earned income" rate on pay and allowances; applications of this nature should be made without delay.

The total income for income-tax purposes of a medical man who has been engaged on war service during the past year is computable as follows: the amount of the profits of his practice (or civil salary, if holding an appointment) for the year to April 5th (or March 31st) *plus* his military or naval pay and those allowances that are treated as subject to income-tax, *plus* the amount of any other taxed income that he or his wife may have. If this total fall below one of the limits referred to in this article a title has arisen to one or more of the forms of relief indicated.

MEDICINE AND THE LAW.

Dr. F. J. Waldo's Annual Report.

THE return made annually to the Common Council by the coroner for the City of London and borough of Southwark has been issued for 1914, and contains, as usual, interesting notes and suggestions upon topics arising out of inquests held by Dr. F. J. Waldo. Some of these relate to cases which have attracted public attention and might be in danger of being forgotten if the attention of a body such as the Common Council were not officially recalled to them, with the possibility that useful results may some day ensue. An example is to be found in the death of a newspaper seller outside Broad-street railway station, who was shot by a man recently released from a private lunatic asylum. The patient had been allowed to go on the condition that relatives took charge of him, and this they had failed to do, with the result that without any difficulty he bought a gun licence, a revolver, and cartridges, which he fired in the street with the fatal result mentioned. In another pistol case recorded by Dr. Waldo the deadly weapon had been bought by a boy without any need to comply with the formal provisions of the Pistols Act, 1903, because its barrel was more than 9 inches in length. The effect of this dangerous proviso in creating a trade in weapons quite as deadly as many of the shorter pistols is well known. An interesting case referred to in Dr. Waldo's report, but not one of the kind which attracts popular attention in reports of inquests, is that of a butcher named Tarrant, manager of a meat store at Mitcham, who died from cutaneous anthrax in Guy's Hospital. At the inquest it came out that a horse and a slaughterman had also died from anthrax, and that two other butchers and a clerk were suffering from it, all cases being most probably connected. The horse belonged to a wharf company and was kept in stables adjoining a slaughter-house, from which meat had been brought to the butcher's establishment at Mitcham by horses which also belonged to the wharf company. This meat was handled by Tarrant. A slaughterman in the Croydon slaughter-house had died from anthrax in Croydon General Hospital without any notification of his death reaching the Croydon coroner. The third butcher referred to was the son of Tarrant's employer, and had handled the contagious swelling on his neck, and the fourth was in the same employment but at Croydon, where he obtained meat from the same slaughter-house. A rider to the verdict at this inquest suggested that anthrax should be made compulsorily notifiable to the medical officer of health of the district in which it occurs, and that all deaths from it should be reported to the coroner. This no doubt is one of the subjects which should be remembered whenever legislation resumes its natural course, and when time permits of the amendment and codification of the law relating to the registration of deaths and to the duties of coroners.

Stevens v. *British Medical Association.*

The Court of Appeal recently heard and dismissed an application for judgment or a new trial made by the unsuccessful plaintiff in the action of Stevens *v.* The British Medical Association. The action, it will be remembered, was based upon criticism of a destructive character directed against "Stevens's Consumption Cure" and republished from the *British Medical Journal* in "Secret Remedies: What They Cost and What They Contain." Specific questions were left to the jury at the trial before Mr. Justice Shearman, and upon them judgment was given for the defendants. The Court of Appeal now delivered judgment without calling upon counsel for the British Medical Association to argue, Lord Justice Swinfen Eady saying that the question was whether upon the facts truly stated the comment was fair and such as could reasonably be made. The jury had had all the facts laid before them and their answers amounted to this, that the words complained of were not libellous because they were fair comment. In his opinion the allegation that the verdict was against the weight of evidence could not be supported, and there had been no misdirection. In his lordship's opinion the trial had been very fairly conducted. In an earlier portion of his judgment Lord Justice Swinfen Eady said that it had been already decided that words containing personal imputations upon the plaintiff might be in law "fair comment." The British Medical Association and our contemporary are to be congratulated upon a judgment which brings to a satisfactory ending the difficult and dangerous litigation involved in cases of this kind.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon (retired) W. Hackett to Devonport Dockyard.

The undermentioned have been entered as Surgeons for temporary service in His Majesty's Fleet:—Alfred Beuthin Danby and Guy Walker Woodhouse (dated May 4th).

The following appointments have been notified:—Temporary Surgeons: H. L. P. Peregrine and S. W. Toulmin to the *Victory*, additional, for Haslar Hospital; F. A. V. Denning to the *Victory*, additional; J. A. Watson to the *President*, additional, for Eastbourne Aerodrome; A. B. Danby to the *Vivid*, additional, for Plymouth Hospital; G. W. Woodhouse to the *Pembroke*, additional, for Chatham Hospital; G. W. Pool and J. C. Gillies both to the *Victory*, additional, for Haslar Hospital; C. H. Browne to the *President*, additional; W. B. Cunningham, to the *Actæon;* R. S. Lawson to the hospital ship *Plassy;* and G. M. Fraser to the *Zealandia*.

ARMY MEDICAL SERVICE.

Temporary Major Cuthbert S. Wallace, from Royal Army Medical Corps, to be Colonel (dated April 29th).

ROYAL ARMY MEDICAL CORPS.

William George Kynaston Barnes, late Deputy-Surgeon-General, Royal Navy, to be temporary Major (dated April 16th).

Stafford Mouritz Cox to be temporary Major (dated April 19th).

The undermentioned are granted temporary rank as follows whilst serving with the War Hospitals named :—Dated April 21st: Napsbury War Hospital: Lancelot William Rolleston to be Major; Arthur O'Neill to be Captain. Springfield War Hospital: Reginald Worth to be Major; Gayton Warwick Smith to be Captain.

The undermentioned to be temporary Captains: Dated April 7th: John Davidson Duncan, late Captain, 5th Battalion, The Black Watch (Royal Highlanders), Territorial Force. Dated April 17th: George Herbert Ward-Humphreys, late Surgeon-Captain, 1st Gloucestershire Engineers, Territorial Force. Dated April 18th: Matthew Leslie Guy Hallwright. Dated April 19th: Harry Young Cameron Taylor, Charles Coley Choyce. Dated May 12th: Temporary Lieutenant Edward A. Evans, Temporary Lieutenant James A. Torrens.

The undermentioned to be temporary Lieutenants: Dated April 9th: Alexander Hugh Dickson Smith. Dated April 12th: Michael Thomas MacMahon and Captain Charles Francis White, 6th Battalion, The Cheshire Regiment. Dated April 14th: Neil Campbell, Lorne Benjamin Graham, Percy Herbert Delamere, Arthur Lincoln Thornley, Arthur Henry Priestley, James Robert Robertson, John Hay Moir, Arthur Thomson, Arthur William Hare, Alexander Mitchell Cowie, Reginald Newton Weekes, Lindsey Willett Batten, Charles Harold Walker McCullagh, Alfred Douglas Bigland, Cyril Meredith Willmott, Alexander Fisher, Joseph McGowan, and Edward Mapother. Dated April 15th: George Harold Wood, Philip Northcote Vellacott, Norman Stephen Gilchrist, Guy Budd Courtney, Frederick John Blackley, Charles Herdman Newton, Robert McCorran Service, John Porter, Frederick James Pierce, Robert John Merson, Frederick William Smith Stone, John Eills Gething, William Alexander Gordon Russell, Langford George Davies, James Hinton Robertson, Thomas Steven McIntosh, Robert Barsham Debenham, and John Caruthers Sale. Dated April 16th: John Scott. Dated April 17th: Theodore Francis Dillon, Herbert Mather Spoor, Herbert Frederick Nolan, Walter Halli Burton MacDonald, Hugh Hamilton Moffat, Alexander Waugh, Edwin Fryer, George Hellyard Darlington, Frederick George Thompson, Frank Graham Wrigley, James Hay Marshall, Arthur Leonard Weakley, Victor Jenner Batteson, and Guy Stuart Goodwin. Dated April 19th: John Rowat, Evan Lewis Hickey, James Jenkins Robb, Alphonsus McGrath, William Claude Percy Barrett, Arthur Macgregor Warwick, Bertram Ernest Wright, Crawford Smith Crichton, Thomas Leathard Wormald, William George Hopkins, Francis Charlesworth, George Stanley Applegate, Robert Macnair Walker, Arthur Herbert Butcher, Arthur Edward Druitt, Herbert Arthur Hancock, Michael Joseph Petty, Richard Kenefick, George Robertson Lipp, John William Nelson Roberts, Tom Stansfield, and Wilberforce John James Arnold. Dated April 20th: William Carnes, Gerald William Stone, Riccardo Stephens, James Clarkson Waithman, George Basil Price, and William Robert Etches. Dated April 21st: Geoffrey Ward Thompson, Henry Carter Thorp, William Arthur Shann, Cunison Charles Finlater, Ralph Paul Williams, William Peach Taylor, Norman Grellier, Hugh Stevenson Davidson, Tom Entwisle Ferguson, John Forbes, David Johnston, and James Charles Martin.

James Erlank is granted temporarily the honorary rank of Lieutenant whilst serving with the Duchess of Westminster's War Hospital (dated May 6th).

Lieutenant Reginald P. Cockin relinquishes his temporary commission (dated April 23rd). Lieutenant Charles B. Pearson, having ceased to serve with the British Red Cross Hospital, relinquishes his temporary commission (dated May 7th).

The undermentioned temporary and honorary Lieutenants are granted the temporary and honorary rank of Captain :—Dated May 7th: Lionel Edward Close Norbury, James Forbes Mackay, and James Duncan Lyle.

INDIAN MEDICAL SERVICE.

Major R. A. Lloyd relinquishes the temporary rank of Lieutenant-Colonel (dated April 15th, 1915).

SPECIAL RESERVE OF OFFICERS.

Major Charles Roberts, having ceased to perform duty with No. 18 Field Ambulance, resigns his commission. Captain Wilson Harold Percy Hey, 2nd Western General Hospital, Royal Army Medical Corps, Territorial Force, to be Captain.

The undermentioned Lieutenants to be Captains: William F. McLean, Robert M. Beath, Thomas Walker, William St. L. Dowse, William McN. Walker, William McK. H. McCullagh, Harry D. Rollinson, and Samuel R. Armstrong.

The undermentioned Lieutenants are confirmed in their rank: William T. Hare, John D. MacCormack, Henry R. Sheppard, and Donald C. Macdonald.

Supplementary to Regular Units or Corps: R.A.M.C.—Lieutenant James T. Cameron resigns his commission.

The undermentioned ex-Cadets of the Officers Training Corps to be Lieutenants (on probation): James Lawson, Norman Bell Graham, Arthur Eaton Richmond, and Geoffrey Bede Egerton. To be Lieutenants (on probation): Patrick Alexander Clements, Robert Orr Colquhoun Thomson, and William Murdoch.

TERRITORIAL FORCE.

Royal Army Medical Corps.

3rd East Anglian Field Ambulance: Captain James Turtle to be temporary Major.

2nd East Lancashire Field Ambulance: Graham Stevenson to be Lieutenant.

1st Lowland Field Ambulance: Captain John W. Leitch to be temporary Major.

2nd Northumbrian Field Ambulance: Cecil Dermot Rogers to be Lieutenant.

3rd Northumbrian Field Ambulance: Robert Raffle and John Steedman Horn to be Lieutenants.

3rd Northern General Hospital: To be Lieutenants: Balfour McKean and Robert Pringle Anderson.

3rd Southern General Hospital: William Stobie to be Lieutenant.

Sanitary Service: Arthur Hamilton Lowe to be Captain, whose services will be available on mobilisation.

Highland Casualty Clearing Station: To be Lieutenants: Joseph Ellis Milne, Charles Forbes, and Alexander Jaffrey Presslie.

5th Northern General Hospital: Lieutenant-Colonel George C. Franklin relinquishes his commission.

Eastern Mounted Brigade Field Ambulance: Vernon Montague Wallis to be Lieutenant.

1st Home Counties Field Ambulance: William Thomas Henderson to be Lieutenant.

1st Southern General Hospital: The undermentioned to be Captains, whose services will be available on mobilisation: George Percival Mills, Andrew Russell Bearn, and Arthur Augustus Russell Green. To be Lieutenant: William Albert Stokes.

2nd London Sanitary Company: To be Lieutenants: Edwin Josiah Messent, Arthur George Whitfeild, and Owen Herbert Peters.

East Anglian Casualty Clearing Station: James Mowat (late Fleet-Surgeon, Royal Navy) to be Major (temporary). To be Lieutenants: Robert Charles Standring Smith and William Joseph Deighan.

Lowland Mounted Brigade Field Ambulance: To be Lieutenants: John Richmond Herbertson, Stuart Spence Meighan, and Thomas Cameron Houston.

4th Northern General Hospital: Christopher Wilfred Sharpley to be Lieutenant.

4th Southern General Hospital: Robert Jaques to be Captain, whose services will be available on mobilisation.

Lowland Casualty Clearing Station: Major John McKie, from the 2nd Lowland Field Ambulance, to be Lieutenant-Colonel.

Northumbrian Casualty Clearing Station: Captain William Simpson, from the 1st Northumbrian Field Ambulance, to be Captain.

Highland Mounted Brigade Field Ambulance: Captain John W. Mackenzie to be temporary Major. Lieutenant Lachlan M. V. Mitchell and Lieutenant Alexander F. Lee to be temporary Captains.

Welsh Border Mounted Brigade Field Ambulance: Lieutenant Walter S. Snell resigns his commission.

Attached to Units other than Medical Units.—Lieutenant Isaac B. Bernstein resigns his commission. Lieutenant Percival T. Rutherford to be Captain. To be Lieutenants: Thomas Dobson Bell, Thomas Porter, Edmund Henri Gonin, and Edward Peter Dawes.

PROMOTION IN THE MEDICAL CORPS OF THE UNITED STATES NAVY.

The United States is considering a Bill to increase the efficiency of the personnel of the navy, and its proposals regarding the Naval Medical Corps, even if complicated, are interesting to the officers concerned and should give hope to the juniors. Medical officers are in future to be commissioned as surgeons with the rank of lieutenant (junior grade) for three years, lieutenant for nine years, and lieutenant-commander for ten years. Officers with less than 22 years' service are promoted to the higher ranks by seniority if there are vacancies for them. But if there are no vacancies, and officers of over 22 years' seniority accumulate at the top of the list and the seniority of the senior 12 averages 22 years a special system for promotion is employed. For each of these 12 a figure of merit is to be calculated, marks being assigned to each for "professional record, knowledge, and reputation," and those with the highest figures shall be promoted into the available vacancies (six, it is expected) according to seniority, the others being retired. The President, in order to make vacancies, may retire officers from each of the two highest ranks, but not more than three from each in any one year. And thus medical officers in the United States navy will get on to the administrative ranks four years or so earlier than do our medical officers, which should make the service there more efficient and the officers on the active list younger and more contented.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8776 births and 5383 deaths were registered during the week ended Saturday, May 8th. The annual rate of mortality in these towns, which had decreased from 19·9 to 17·3 per 1000 in the four preceding weeks, further fell in the week under notice to 15·5 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of last year. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 17·8, against 18·8 per 1000 in London. Among the several towns the death-rate last week ranged from 6·1 in Lincoln, 7·7 in Enfield, 8·1 in Southend-on-Sea, 8·2 in Hornsey and in Smethwick, and 8·7 in Wimbledon to 23·7 in Barrow-in-Furness, 23·8 in Walsall, 24·3 in West Hartlepool, 24·5 in Wigan, and 25·2 in Middlesbrough.

The 5383 deaths from all causes were 639 fewer than in the previous week, and included 557 which were referred to the principal epidemic diseases, against 689 and 711 in the two preceding weeks. Of these 557 deaths, 276 resulted from measles, 121 from whooping-cough, 67 from infantile diarrhœal diseases, 51 from diphtheria, 30 from scarlet fever, and 12 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·6, or 0·4 per 1000 less than in the previous week. The deaths attributed to measles, which had been 426, 389, and 392 in the three preceding weeks, fell to 276 last week, and caused the highest annual death-rates of 2·4 in Salford, 2·8 in Sheffield, 3·1 in Tottenham and in St. Helens, 3·5 in Darlington, 4·0 in Northampton and in West Hartlepool, 4·4 in Walsall, 4·5 in Middlesbrough, and 6·3 in Barrow-in-Furness. The deaths referred to whooping-cough, which had declined from 167 to 142 in the four preceding weeks, further fell to 121 last week; the highest death-rates recorded from this cause were 1·2 in Willesden and in Walthamstow, 1·4 in South Shields, 1·7 in Reading, 2·0 in Swindon and in Aberdare, and 3·4 in Wigan. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 63, 65, and 73 in the three preceding weeks, fell to 67 last week, and included 17 in London, 7 in Liverpool, 5 each in Birmingham and Sheffield, and 4 in Salford The deaths attributed to diphtheria, which had been 55, 49, and 56 in the three preceding weeks, declined to 51 last week, of which 9 occurred in London and 3 in Great Yarmouth. The deaths referred to scarlet fever, which had increased from 16 to 34 in the five preceding weeks, fell to 30 last week, and included 5 in London, 3 each in Liverpool, Middlesbrough, and Newcastle-on-Tyne, and 2 each in Birmingham and Leeds. The fatal cases of enteric fever, which had been 11, 8, and 12 in the three preceding weeks, were again 12 last week, and included 6 in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2422, 2369, and 2377 at the end of the three preceding weeks, had increased to 2384 on Saturday last; 307 new cases were admitted during the week, against 263, 259, and 316 in the three preceding weeks. These hospitals also contained on Saturday last 1214 cases of diphtheria, 220 of measles, 63 of enteric fever, and 14 of whooping-cough, but not one of small-pox. The 1384 deaths from all causes in London were 187 fewer than in the previous week, and corresponded to an annual death-rate of 16·0 per 1000. The deaths referred to diseases of the respiratory system, which had been 469, 392, and 346 in the three preceding weeks, further declined to 289 in the week under notice, but were 68 in excess of the number in the corresponding week of last year. The deaths from influenza numbered 20, against 39, 27, and 30 in the three preceding weeks.

Of the 5383 deaths from all causes in the 96 towns 211 resulted from different forms of violence and 398 were the subject of coroners' inquests, while 1567 occurred in public institutions. The causes of 32, or 0·6 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Leeds, Bristol, West Ham, Bradford, Hull, and in 74 other smaller towns. Of the 32 uncertified causes of death, 9 were registered in Birmingham, 4 in Liverpool, and 2 each in St. Helens, Southport, Warrington, Sunderland, and South Shields.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1231 births and 815 deaths were registered during the week ended Saturday, May 8th. The annual rate of mortality in these towns, which had been 20·9, 18·5, and 20·2 per 1000 in the three preceding weeks, declined to 18·1 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 19·7, against a corresponding rate of 17·8 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 10·2 in Kirkcaldy, 11·7 in Leith, and 11·8 in Coatbridge, to 20·3 in Edinburgh, 20·6 in Perth, and 24·0 in Greenock.

The 815 deaths from all causes were 94 fewer than in the previous week, and included 142 which were referred to the principal epidemic diseases, against 128 and 150 in the two preceding weeks. Of these 142 deaths, 65 resulted from whooping-cough, 47 from measles, 15 from infantile diarrhœal diseases, 7 each from scarlet fever and diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 3·2, against a corresponding rate of 1·6 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 90, 75, and 82 in the three preceding weeks, declined to 65 last week, and included 34 in Glasgow, 10 in Edinburgh, 9 in Dundee, and 3 in Greenock. The deaths referred to measles, which had been 19, 26, and 36 in the three preceding weeks, further rose to 47 last week, of which 35 were registered in Glasgow, 7 in Aberdeen, and 2 in Clydebank. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 10, 12, and 9 in the three preceding weeks, rose to 15 last week, and included 6 in Glasgow and 2 each in Aberdeen and Leith. The deaths attributed to scarlet fever, which had been 7, 7, and 11 in the three preceding weeks, fell to 7 last week, and comprised 3 in Glasgow, and 2 each in Aberdeen and Paisley. The deaths referred to diphtheria, which had been 7, 6, and 12 in the three preceding weeks, fell to 7 last week, and included 2 each in Glasgow, Paisley, and Motherwell. The fatal case of enteric fever occurred in Edinburgh.

The deaths referred to diseases of the respiratory organs, which had been 178, 145, and 153 in the three preceding weeks, declined to 118 in the week under notice, but were 2 in excess of the number in the corresponding week of last year. The deaths attributed to violence numbered 23, against 30 and 25 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,212,380 persons at the middle of this year, 592 births and 463 deaths were registered during the week ended Saturday, May 8th. The annual rate of mortality in these towns, which had been 22·1, 22·4, and 19·1 per 1000 in the three preceding weeks, rose to 19·9 per 1000 in the week under notice. During the first five weeks of the current quarter the mean annual death-rate in these towns averaged 21·5, against corresponding rates of 17·8 and 19·7 per 1000 in the English and Scotch towns respectively. The death-rate last week was equal to 23·7 in Dublin (against 16·0 in London and 18·4 in Glasgow), 16·7 in Belfast, 20·4 in Cork, 15·2 in Londonderry, 23·0 in Limerick, and 13·3 in Waterford, while in the 21 smaller towns the mean death-rate was 19·7 per 1000.

The 463 deaths from all causes were 19 in excess of the number in the previous week, and included 33 which were referred to the principal epidemic diseases, against 41 and 35 in the two preceding weeks. Of these 33 deaths, 10 resulted from measles, 9 each from whooping-cough and infantile diarrhœal diseases, 3 from diphtheria, and 1 each from enteric fever and scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·4, against corresponding rates of 1·6 and 3·2 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had been 5, 13, and 11 in the three preceding weeks, were 10 last week, of which 8 occurred in Belfast. The deaths referred to whooping-cough, which had been 11, 20, and 9 in the three preceding weeks, were again 9 last week, and included 5 in Dublin and 2 in Belfast. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had increased from 3 to 10 in the four preceding weeks, were 9 last week, and comprised 6 in Dublin, 2 in Belfast, and 1 in Londonderry. The 3 deaths from diphtheria occurred in Dublin, and were slightly in excess of the average in recent weeks. The fatal case of enteric fever was registered in Dublin and that of scarlet fever in Waterford.

The deaths referred to diseases of the respiratory system, which had declined from 158 to 84 in the four preceding weeks, further fell to 76 in the week under notice. Of the 463 deaths from all causes, 137, or 30 per cent., occurred in public institutions, and 6 resulted from various forms of violence. The causes of 15, or 3·2 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the large English towns the proportion of uncertified causes did not exceed 0·6 per cent.

Correspondence.

"Audi alteram partem."

SANITATION IN INDIA.

To the Editor of THE LANCET.

SIR,—In your issue of March 6th a joint letter from Professor R. Tanner Hewlett, Colonel W. G. King, and Professor W. J. Simpson was published under the above heading. The responsible positions that these three gentlemen occupy in educational sanitary circles in London secure every consideration for contributions from their pen, and I am authorised to say that the Government of India are in entire agreement with the views set forth in the joint letter in question as regards the value of British Diplomas in Public Health. Indeed, in the resolution to which the writers refer it is clearly laid down that a British Diploma in Public Health is a *sine quâ non* for appointment either as a Deputy Sanitary Commissioner, or, for the present at least, as a first-class health officer. The Government of India, too, fully concur in the view that it is distinctly desirable that Indian candidates for important sanitary appointments should regard training in Great Britain as the foundation of their careers. In this connexion I may state that since 1912, 27 Indians holding British Diplomas in Public Health have been appointed to the Sanitary Department—11 as Deputy Sanitary Commissioners and 16 as first-class health officers. In these circumstances it is scarcely fair to hold the Government of India responsible for the private opinions of a Provincial Sanitary Commissioner, especially when it is borne in mind that the only evidence as to the existence of such opinions is that furnished by the unsupported statements of a disappointed candidate.

I am, Sir, yours faithfully,
P. LUKIS, M.D., F.R.C.S. (Surgeon-General),
Director-General, Indian Medical Service.
Simla, April 15th, 1915.

CEREBRO-SPINAL MENINGITIS: MENINGOCOCCI FOUND IN PERIPHERAL BLOOD FILMS.

To the Editor of THE LANCET.

SIR,—At the end of a short article under the above title in THE LANCET of April 10th I asked the question, "Are the organisms to be commonly found in films made from the peripheral blood in cases of cerebro-spinal fever, and is this a practical method of diagnosis, or are the meningococci only to be found in the septicæmic type of the disease?"

In view of the frequent inquiries I receive from various correspondents, I think it would save some confusion if I now tried to answer that question. 1. Sir William Osler kindly wrote: "I was very much interested in the figures in your paper in to-day's LANCET, as the first demonstration of the meningococci in the blood was made in my wards. We never had a case with so many in the leucocytes, as shown in your Figures 4, 5, and 6. On several occasions we got the cultures when it was difficult to find the organisms by simple staining." 2. Dr. Mary Williams, judging from her letters in the *British Medical Journal* of April 3rd and THE LANCET of April 17th, seems to have been exceptionally fortunate. She says: "I found the germ in 80 consecutive cases, and found it more readily in this manner than from the throat. ...... If there were any symptoms showing involvement of the nervous system, we found the germ in the blood. ...... We had cases of every degree of severity—from a man who started with agonising pain in the head and was dead in a few hours to cases in which diarrhœa, giddiness, and malaise of a slight degree were the only symptoms. ...... In many cases the latter (meningococci) were in the leucocytes. ...... In blood the meningococci I have seen often have a capsule. ...... Personally I believe this to be the method of diagnosis which will shortly be widely adopted." 3. I have heard from two or three bacteriologists, who all state they have entirely failed to find the organisms in the blood of any of the cases they have examined. 4. Thanks to Dr. A. D. Edwards, medical officer of health of Bournemouth, I have had an opportunity of examining films made from ear or finger blood of six undoubted cases of cerebro-spinal fever. One of these was a fulminating, rapidly fatal one. After a prolonged and careful search of these films I have been quite unable to recognise any meningococci, either free or intracellular in position, in any of these. The only case in which I found the organism is the one described and that was an intensely septicæmic type. The patient had "a purpuric rash on the brow and face," and later on extravasation of blood on the trunk. I should think that meningococci could have been found in the blood taken from any part of the body, but what I did notice casually at the time was that when I pricked the lobe of the left ear it felt firm, and somewhat indurated, and it might even have been the seat of the purpuric rash, or even an area in which there was extravasation of blood, but the ward was somewhat dimly lighted and I did not observe this. However, it occurred to me afterwards that it would be a good plan to make the film from the blood taken from a spot of the rash. I therefore wrote to Dr. Edwards: "Please do not trouble to send me any more films from cases of cerebro-spinal fever, unless you happen to meet with another of the septicæmic type. It might, in future, be worth while taking the blood from a spot should the rash be present, just as is done in making cultures from the blood of the rose-coloured spots in the case of typhoid fever."

I think we may, therefore, conclude: 1. That meningococci may be occasionally found in the peripheral blood, but only in rare cases. 2. That this method of examination cannot be used as a means of diagnosis. 3. That Dr. Mary Williams's remarkably successful results have not been obtained by other observers during the present epidemic.

I am, Sir, yours faithfully,
Bournemouth, May 6th, 1915. ALFRED C. COLES.

THE BALNEOLOGICAL COMMITTEE OF THE ROYAL SOCIETY OF MEDICINE AND ITS METHODS.

To the Editor of THE LANCET.

SIR,—Early in February of this year I received a letter from the secretaries of the above recently formed committee—Dr. R. Fortescue Fox and Dr. J. Campbell McClure—intimating the formation of the committee, on the suggestion of the War Office, to collect information and give advice to the War Office regarding "the scientific distribution of wounded soldiers among the British health resorts." In accordance with the request made I furnished a preliminary report on the nature of the establishment of which I am the medical superintendent, and an account of the facilities as regards baths and physiotherapy available. On Feb. 22nd I received a further letter intimating that the following resolution had been just passed at a meeting of the committee:—

> That no bathing establishment should be placed on the list of the War Office which does not allow medical men other than the resident physician to send their patients freely for treatment.

I was asked to state definitely the practice of the hydro in this respect without delay. I did so, and intimated that I was medical superintendent of the hydro and took charge of all details with regard to the treatment of invalids, and informed them that the lay manager of the hotel—albeit a very competent and energetic gentleman—took no charge whatever of the baths or treatment arrangements. As regards patients from outside doctors, I intimated that nine-tenths of my patients were sent me through the kindness of "outside men" in all parts of the country, as well as from Peebles (town and county). These gentlemen invariably left me to deal with the patients according to my own discretion, making some suggestion perhaps occasionally by 'phone message or letter. In short, I intimated what seemed almost superfluous, that I actually discharged the duties of a medical superintendent. I also stated that I would be glad to hear that the committee had no intention of starting a boycott—which under the circumstances I considered most uncalled for—as I had expressed complete willingness to place the establishment, so far as my directors would permit and was humanly possible, at the disposal of wounded soldiers and officers, and to treat the former, at any rate, gratuitously.

I begged for an early reply, but received none whatever until, on my again writing about March 24th to Dr. Fox, personally, expressing rather pointed criticism of the methods on which the whole business was being conducted, I got a personal reply from Dr. Fox. This began as follows: "By this time you would have received Dr. McClure's letter, and understand the real position. He will write you further ...... "; with some other remarks which I need not repeat. As Dr. Fox had placed a late postage extra $\frac{1}{2}d.$ stamp on his note he evidently considered the matter urgent, so I wired at once that I had received no letter, first or second, from Dr. Campbell McClure. I confirmed the wire by letter, and received no response whatever from either secretary. I waited a week and then wrote stating exactly where we stood, and requested the further letter from Dr. McClure promised. On April 1st I received one as follows signed by Dr. Fox: "On receipt of your letter of 24th my colleagues and I were regretfully obliged to conclude that the establishment of medical baths at Peebles was not of such a nature as described in the resolution of which I sent you a copy on Feb. 22nd." I replied, expressing regret at the very ill-considered action of the committee, and have since been in communication with the War Office direct.

Now, Sir, I would like to point out one or two further facts having a bearing on this matter. Last summer Dr. Fox visited this establishment and had a long interview with me, and at that date expressed a desire that it should be "thrown open" so that any medical man could come and prescribe baths or physical treatment for his or her patients, and generally take a hand in "running the show." I do sincerely hope I am not unusually selfish, but as I happen to be physician-in-charge and have a monopoly of the practice—which is really what the Americans call "referred" practice—I did not then happen to see Dr. Fox's point of view as regards private patients. The hotel company might have something to say also if I turned the place inside out and broke my contract with them. Dr. Fox's idea, first promulgated to me last August, now turns up again from the Balneological Committee, dated from 36, Devonshire-place—Dr. Fox's house.

In his letter of March 22nd Dr. Fox tells me "all the considerable bathing establishments have opened their doors in this emergency." I have investigated this matter, and two days ago received a letter from the physician in charge of the largest establishment of its kind in the country, possessing very elaborate and extensive baths which cost upwards of £20,000, and my friend informs me that, quite apart from "opening their doors" in the manner described, they had never even been communicated with, but in any case they were packed with visitors, very largely patients. I find difficulty in reconciling the two statements.

Some years ago you gave me the courtesy of your columns (August 12th, 1911) for a short article on Institutional Hydropathic Treatment and Spa Treatment, in which I endeavoured to show there was a special field for each. I have personally been only engaged in the former branch of hydrotherapeutic practice, but it has always struck me that the spa physician has not only adopted, for the most part, an attitude almost contemptuous to such men as myself, but further in regard to institution work he is largely "without understanding." He appears to be incapable of absorbing the idea that such an establishment might be run by a medical man much after the manner of a tuberculosis sanatorium—or a private asylum—with, of course, lay assistance, in various ways.

Dr. F. A. de Thierry Mouillot, a past president of the Balneological Society, judging from a recent article in the *British Medical Journal*, would seem to be waking up to the possibility. But past experience of spa physicians would lead me to conclude that men engaged like myself in institution treatment are by them regarded as "very small beer." Possibly on the ground that Dr. Mouillot refers to—viz., that the institution is run in large measure for the profit of lay shareholders, and also advertises itself in the medical journals at times. But might I remind Dr. Mouillot and Dr. Fox and other spa physicians that while they themselves do not have such advertisements the baths committee of this or that municipality sometimes advertises its "Queen of watering places" profusely in railway stations and by posters, while the spa physician reaps the benefit.

Now Dr. Fortescue Fox, a quondam spa physician, wishes to coerce me, to run the medical side of this establishment on *his* lines or suffer *military* boycott at any rate. I cannot meet his views. Several hundred "Tommies" have had baths of sorts each week here since early March at a charge of one halfpenny for a towel! This has led to much overtime and Sunday labour for the staff, but the men, now gone, were very appreciative, as were their officers.

I hope, in spite of the Balneological Committee, to have many opportunities of doing "my bit" during the coming year, but I cannot face the inevitable confusion and upset which the carrying out of the wishes of Dr. Fox and his colleagues would cause in a place of this kind—among the bath attendants and the ordinary *clientèle*. I am, Sir, yours faithfully,

THOMAS D. LUKE, M.D. R.U.I.

The Hydro Hotel, Peebles, May 1st, 1915.

THE TREATMENT OF CORNS.

To the Editor of THE LANCET.

SIR,—Measures for the treatment of this often extremely painful affection must be divided into two groups: (1) those which get rid of the corns and (2) those which prevent their recurrence. The ordinary treatment for a painful corn is to cut it down as much as possible, without causing bleeding, either straight away or after a preliminary soaking with hot water or some chemical, and then for a few days apply a protective dressing, such as a corn-plaster or lint and strapping, until the pain and tenderness have gone out of it. The patient then resumes his ordinary vocation entirely relieved; but after a few weeks or months the corn re-appears as before, and treatment is again required. Such merely palliative treatment, the stock-in-trade of thousands of chiropodists, should only be carried out alone in exceptional cases; we should aim at *curing* the corn—i.e., removing it and *preventing its recurrence.*

1. *To get rid of the corn.*—The foot is soaked in hot water (105° F.) for half-an-hour, the hard part of the corn is then gently rubbed away with a file, and glacial acetic acid applied to the base of it. It is then covered with india-rubber sheeting, of the same quality as that used by dentists in making a rubber dam, fixed in position by two elastic bands around the foot or toe, one distal and one proximal to the corn. This is removed morning and evening and the acid reapplied for two to three days until the site of the corn begins to feel tender; application of the acid is then stopped and the rubber covering used alone. By this time the corn with the immediately surrounding skin is white and dead-looking; after another two days, if not before, the core of it can be completetly removed by rubbing firmly with a gauze swab. The rubber is now left off altogether; lint spread with boric ointment is applied to the site of the corn, and reapplied twice daily for two or three days more. The surrounding parts then soon regain their normal appearance. For this treatment to be effectual the patient should not use the foot while it is being applied. If the corn is inflamed the inflammation must be entirely relieved by fomentations and rest in bed before this treatment can be carried out.

2. *To prevent its recurrence.*—To do this one must remove the causes producing it, the two commonest being a contracted state of the toes and improperly shaped boots. A condition frequently met with is where the toe is hyper-extended at the metatarso-phalangeal joint and flexed at the proximal interphalangeal joint; this deformity, when exaggerated, as it often is in the case of the second digit, is known as "hammer-toe." The result of this deformity is a corn on the sole of the foot beneath the head of the metatarsal and another on the dorsum of the toe over the prominent interphalangeal joint. No amount of treatment directed to the region of the corn will prevent its recurrence if the contracted state of the toes be not remedied. The extensor tendons of each contracted toe must therefore be divided subcutaneously; in a severe case it may be necessary to divide the flexor tendons too. Thereafter the toes must be prevented from contracting again by gentle passive stretching morning and evening. If there be present an actual condition of "hammer-toe" it must be dealt with by excision of the joint in the ordinary manner.

Having got the toes straight, and having removed the corns, it is now essential that the patient be fitted with boots the shape of his feet. These must be made to measure on fresh lasts by a skilled bootmaker; it is useless to attempt to fit such a patient with ready-made boots or shoes. For often one foot is $\frac{1}{4}$ in. to $\frac{1}{2}$ in. longer than the other, and when one boot is a good fit the other is too big or too small. Also, only rarely is the boot broad enough in the tread to allow the foot to spread properly, and it is almost invariably the wrong shape—that is, instead of being "straight on the inside," with the end of the boot opposite to the big toe, the end is opposite the third toe, so that the former is pushed out, producing in time the deformity of hallux valgus. When the big toe is pushed out by an improperly shaped boot it either pushes the other toes out, so that the whole foot "treads over" the outer side of the boot, or less commonly it overrides the second toe, or causes such cramping of the toes that any toe may overlap or be overlapped by the next one. No permanent improvement can be effected in these deformities, and in the corns produced by them, unless the patient be fitted with correct footwear. Apart from the latter, the best treatment for slight hallux valgus or for overlapping toes is the wearing of digitated socks or stockings during the daytime and the use of indiarubber "toe-dividers" at night, which treatment must be persisted in for some years.

When consulted by a chronic case of painful corns our practice should be to send the patient to hospital or nursing home and at once commence the acetic acid treatment. On the second or third day if any toes be contracted the tendons keeping them so are divided subcutaneously with a fine short-bladed sharp-pointed tenotome, under gas and oxygen; and on the fifth or sixth day the bootmaker arrives to measure the now much improved feet for suitable boots; at the end of another week the boots are ready, the corns have been got rid of, the shortened tendons have now all become lengthened, and the patient can leave for a week's convalescence at home. The only after-treatment necessary is gentle stretching of the toes into the over-corrected position, carried out by the patient's own fingers for a minute or two morning and evening for some months, and the long-continued wearing of boots and shoes made on the new lasts. The patient thus obtains permanent relief from painful corns from which he may have been suffering for a generation.

With regard to digitated socks—1. Their use is seldom necessary for all the toes; as a rule, only one or at the most two toes require restraint. 2. Unless they fit perfectly, they soon cause sores and blisters. 3. It is better, therefore, for the patient to wear ordinary socks half a size larger than he usually takes, and convert them into digitated socks for the particular toes required by sewing the plantar and dorsal parts of the sock together parallel to and on either side of the toe which is to be kept straight. A pocket is thus formed into which the affected toe can be slipped. 4. When digitated socks are worn, whether of the kind just described or not, foot powder must be sprinkled between the toes every morning to avoid chafing.

Hallux valgus.—As regards the treatment of the corn produced by this deformity, much depends on the position of the abnormal bony projection beneath it, and upon the presence or absence of a bursa beneath the corn. If the bony projection is quite clear of the ground when the patient is standing, as is usually the case, it should be removed by operation, the corn having been previously got rid of as described; but if it form part of the bone on which the patient stands removal by operation is contra-indicated. Then again, if there be a bursa beneath the corn—that is, if the condition known as bunion be present—no amount of local treatment can get rid of both the corn and the bursa; and after a course of local treatment to the former the latter must be excised by operation. Such an operation is, however, not worth doing if the bony projection beneath cannot, for the reason given above, be chiselled away, and therefore there are some cases of this condition which *cannot be cured:* these must be treated palliatively by the wearing of a rubber or papier maché shield to protect the part, in conjunction with specially shaped boots and shoes of soft leather.

It may be added that the circular corn-plasters are often very useful in protecting a corn from pressure, especially in the sole of the foot, under the head of a metatarsal bone. Such a corn is difficult to cure, because the patient will not lie up for a sufficient length of time, and protection is often the only treatment he will accept.

I am, Sir, yours faithfully,

PAUL BERNARD ROTH, F.R.C.S.Eng.,

Surgeon, Kensington General Hospital; Senior Orthopædic Clinical Assistant, London Hospital; Captain, R.A.M.C. (S.R.).

Harley-street, W., April 30th, 1915.

TREATMENT OF "INCRUSTED CYSTITIS" BY SUPRAPUBIC DRAIN AND INTRAVESICAL INJECTION OF LACTIC BACILLI.

To the Editor of THE LANCET.

SIR,—With reference to the letters on this subject in THE LANCET of May 1st and 8th the following may be of interest. During 1905 and 1906 while working at the subject of suprapubic drainage I frequently washed out patients' bladders affected with "incrusted cystitis" with acidum aceticum dilutum (℥ ii. ad O i.) and acidum hydrochloricum dilutum (℥ i. ad O i.), and the solution of the phosphates was rapid and painless unless the acid happened to flow over an ulcer or crack in the skin when it would give rise to considerable pain. It seemed to me at the time that the action of the acid gave rise to a much larger quantity of mucus in the urine than had been present before. Whether this was due to mere chemical precipitation from the alkaline solution or to a stimulation of the cells to produce more was not clear, but the persistence of excess of mucus after lavage was stopped pointed to the latter as being the cause. The results were better if the bladder was washed out with a dilute solution of sodium hydrate after the acid had acted, and if this washing out was also done before the acid was employed, so as to dissolve the mucin, the solution of the phosphates by the acid was very rapid.

It would be valuable to hear the opinions of those who have used the lactic bacilli method on these points—viz., Does the treatment give rise to more or less mucin formation than does treatment by lactic acid alone, and is the action of the acid which is produced bacteriologically in a nascent state greater and more rapid on phosphates and bacilli *in vitro* than the action of ordinary lactic acid in solutions of equal strength? It seems to me that the question of disinfection in such cases is so closely bound up with the removal of the foreign body (phosphate) that observations on these points will be most valuable. This is especially true just now when bullet wounds of the bladder and surrounding bones and soft tissues are giving rise to so much misery, suffering, and death.

I am, Sir, yours faithfully,
G. H. COLT.
Aberdeen, May 10th, 1915.

STOMACH *V.* HEART IN RELATION TO PRÆCORDIAL PAIN AND SUDDEN DEATH.

To the Editor of THE LANCET.

SIR,—The following passage occurring in Sir R. Douglas Powell's interesting letter in THE LANCET of May 1st confers upon the algesic symptom the status of a recognised place in the contents of the angina pectoris syndrome: "There is, of course, no doubt as to the existence and in some degree the diagnostic value of localised 'algesia,' or, as I should prefer to say, surface pains, and points of tenderness in angina pectoris, as in association with most forms of visceral suffering, and a nerve centre may become hypersensitive from repeated excitation." A state of hypersensitiveness in nerve centres is in other words a state of neurosis. This view is in accordance with that expressed in my letters to THE LANCET of April 3rd and 24th. But if the presence of a neurosis be admitted, the conclusion follows that the status of the neurosis in the syndrome is that of predisposing cause. Sir Douglas Powell refers to another solution to which he attaches greater importance—namely, that coronary disease is the operative causal agency in the case which had been reported by me. With submission to the better opinion of Sir Douglas Powell, I would bring certain facts before your notice for consideration which appear to me to place insuperable obstacles in the way of the application of the Jennerian doctrine to cases of the type which I have described.

Precise methods of cardiographic record recently introduced and employed in research furnish ample proof that the myocardial functions of Gaskell, without exception, are working after a normal manner during the course of the anginal seizure. Hence the theories of claudication and cardiac spasm become untenable. The hypothesis of the "tender" artery is open to the objection that arteries lying near the surface which offer direct means of examination may pass through all stages of degenerative change without manifesting any signs of tenderness upon pressure. Moreover, post-mortem examination not infrequently reveals extensive coronary and aortic disease in cases which had sustained for many months previous to death exceedingly high blood pressure without the patient having been conscious of any præcordial or other thoracic pain.

Difficulties which beset the explanation of the following list of phenomena occurring in the angina pectoris upon any hypothesis based upon coronary or aortic disease, as the predisposing cause, are apparent.

1. Pain in the course of intercostal nerves. Spasm of intercostal and recti abdominis muscles, algesia, vaso-motor disturbances including increased systemic blood pressure, cardiac symptoms, vagal inhibition, eructations of flatus, retching, vomiting, the influence of gastric hypertension in the excitation of seizures, and the effects of gastric deflation in determining the subsidence of seizures.

2. Post-mortem statistics indicate that the frequency of coronary disease is not in greater ratio in subjects of angina pectoris than in subjects of indifferent visceral arterial disease. In a series of 398 cases of visceral arterial disease, the subjects dying at an average age of 45 years, Dr. Harlow Brooks, professor of pathology, New York University, observed in the course of his ordinary necropsial duties 270 instances of coronary disease, a ratio equal to 67·8 per cent.[1] Some figures relating to the frequency of coronary disease in the angina pectoris are available for comparison. In 244 cases of angina pectoris collected by Tacchi,[2] Sir John Forbes,[3] Lussana,[4] Wilde,[5] Gothair,[6] Huchard,[6] and Osler,[7] coronary disease was observed in 52 per cent. of the subjects. The largest ratio appears in Professor Osler's list, in which coronary disease was found in 13 out of 17 cases, the percentage being 76·4.

3. Professor Osler gives the age periods of mortality from angina pectoris. I quote from his Lumleian lectures on the subject. Under 30 years, 9 cases; between 30 and 40, 41 cases; between 40 and 50, 59 cases; between 50 and 60, 80 cases; between 60 and 70, 62 cases; between 70 and 80, 13 cases; above 80, 3 cases.[8]

According to Professor Osler's figures, which correspond fairly accurately with those of the

Registrar-General, the incidence of death from angina pectoris after 60 years of age declines year by year until at 80 it approaches nullity, whereas during the same age periods among the general public the incidence of coronary disease is increasing year by year until it reaches universality.[9]

Sir Douglas Powell observes that the fact of præcordial pain appearing after marked exertion is suggestive of aortic disease. But permit me, Sir, to point out to you that muscular effort excites paroxysms in a class of cases which boast for their pathology the segmentary neuroses. I refer to the class of paroxysmal spasmodic complaints associated with the musculature of the alimentary canal and other abdominal visceral cavities. Included in this class are: trismus of tetanus, palato-pharyngeal spasm of hydrophobia, œsophagismus, gastrismus, entero-spasm, biliary and renal colic, colismus, tenesmus, strangury and utero-spasm; paroxysms in all these instances alike are induced or aggravated by muscular effort. I may also add in this connexion that the spasm in certain of these disorders is reduced, as in the angina pectoris, by administrations of nitro-glycerine.

If the angina pectoris be included in this class of paroxysmal spasmodic disorders, as suggested by Heberden, a rational explanation is furnished for every symptom of the complaint and for every phase of it.—I am, Sir, yours faithfully,

Streatham Hill, May 4th, 1915. H. WALTER VERDON.

THE MEDICAL PROFESSION AND THE NEEDS OF THE ARMY.

To the Editor of THE LANCET.

SIR,—May I be allowed some space in your columns to suggest to your readers, including those in authority, a few points as to why there exists dissatisfaction among medical men who have already given their services to the army, and also why some who have not yet joined are hanging back from so doing.

The leading article in THE LANCET of May 8th puts the case of the War Office plainly and judicially, but from what I gather from those who are serving as medical officers in the Territorial Forces the causes of dissatisfaction are other than those to which you refer.

I can vouch for the following matters:—Grievances settle round two points, pay and promotion, not so much *per se* but as regards the inequality between the Territorial Forces and the forces popularly known as Kitchener's Army. A lieutenant in the R.A.M.C. (Territorial) gets 14*s.* per diem, together with 3*s.* for billet and 1*s.* 9*d.* per diem for rations. A lieutenant in "Kitchener's Army" gets £1 4*s.* per diem and £60 on release from service. Promotion, too, is slow; I know of at least one instance in which an officer was gazetted some seven months ago, he is still a lieutenant, although he has been doing a major's work (in command of a section) all the winter and spring. A recent application for promotion, backed by his commanding officer, was refused on the ground that by the Territorial Forces Regulations a lieutenant R.A.M.C. must have seen at least three years' service. Other executive branches of the service get rapid promotion; for instance, a man who was gazetted second lieutenant in October, 1914, in the Army Service Corps is now a captain.

The Territorial R.A.M.C. men only joined originally for home service, but an Army Order has been made insisting on service anywhere required, whether abroad on active service or in India; and it must be remembered that Territorial R.A.M.C. are frequently almost all elderly men, for the younger men naturally join Kitchener's Army. The question of pay is not the only grievance. The question of promotion is felt to rankle, for the refusal of it seems to show a grudging recognition of the spirit which led elderly practitioners to volunteer, and which the War Office would do well to foster rather than, as it is doing, to dash.

I am, Sir, yours faithfully,

May 11th, 1915. H. P. CHOLMELEY.

To the Editor of THE LANCET.

SIR,—Many eligible men still abstain from giving up lucrative practices and offering their services for the following reasons:—

1. All medical officers, though their work and risks may be identical, are not treated alike. Treatment depends on whether a man is: (*a*) a temporary Royal Army Medical, in which case he receives the rank of lieutenant but the pay of 25*s.* a day (major's pay); (*b*) a permanent Royal Army Medical, in which case he receives the rank of captain and draws captain's pay; or (*c*) a Territorial Royal Army Medical, in which case he receives the rank and pay of lieutenant (14*s.* a day pay and 4*s.* 9*d.* allowances at times). The Territorial medical officer has almost invariably made bigger sacrifices, yet receives the least pay.

2. Certain medical officers acting in a combatant capacity have offered to transfer to the R.A.M.C. and have not been permitted to. (Their applications have not even been forwarded.)

3. Many R.A.M.C., both Regulars, Temporary, and Territorial, have for months past been kept at home only partially employed when they have repeatedly asked to be allowed to go abroad, their work being carried on at home by civilian doctors. Is it not reasonable for them to ask themselves whether the War Office can really be so very short, as it does not appear to make the best use of what material it already has at its disposal.

I suggest the following as a remedy: 1. Do away with the arbitrary distinction between Territorial and Regular. Classify, if necessary, into home and imperial service medical officers, but let all army doctors come under the same departmental control and let them all receive the same scale of pay. 2. As it takes approximately five months to train a combatant officer, but five years to train a medical officer, let all doctors at present serving in a combatant capacity revert to their professional work. 3. Do away with the medical officer for regimental work at home and substitute the part-time civilian practitioner, who could, without much heavier work, see the 20–30 army at the same time as he sees his panel patients. And lastly, if it were found that the Admiralty have a surplus of medical officers, could no amicable arrangement be arrived at whereby either a united medical service could be formed or even a united medical reserve service on which either could draw as requirements arose?

I am, Sir, yours faithfully,

May 7th, 1915. LIEUTENANT R.A.M.C. (T.F.).

---

[9] American Journal of the Medical Sciences, May, 1906.

The War.

THE CASUALTY LIST.

THE casualty lists published since our last issue contain the following names of medical officers:—

Wounded: Lieutenant P. Cagney, R.A.M.C. (attached 2nd Essex Regiment); Lieutenant R. C. Neil, R.A.M.C. (attached 6th Middlesex Regiment); Surgeon Charles F. A. Hereford, R.N.V.R.

Missing (believed to be prisoner): Surgeon Probationer William W. K. Brown, R.N.V.R. (H.M.S. *Maori*).

Captain Howard Tomlin Hunter, 6th Northumberland Fusiliers, T.F., who was killed at Ypres on April 26th, was an M.B., B.S. Durham, 1910. He received his first commission in the Territorial Forces in 1906 and was gazetted captain in 1912.

MEDICAL ORGANISATION AT THE FRONT.

A most timely article has been communicated to the press by an "Eye-Witness present with General Headquarters," in which the whole subject of the treatment and evacuation of the wounded is ably dealt with. The fortunes of the wounded man from the time of his wound until the reception in a base hospital have been described in these columns. In a way the whole story will be familiar to medical men and to some extent to the public; but "Eye-Witness" has given a consecutive narrative, while hitherto only chapters dealing with this, that, or the other point have been published, and considerable experience has sometimes been assumed for the reader.

The narrative begins by describing the organisation in the field, at the head of which is the Director-General. "Eye-Witness" says:—

> The medical organisation in the field consists at the front of two kinds of formations, those of armies and those of divisions. The former are under a Director of Medical Services, who, while responsible for the technical working of all units and branches of the medical service within his army, has under his direct control the large clearing stations established within easy reach of the railway, the motor ambulance convoys, and all sanitary arrangements in the particular army area. The divisional formations are under the Assistant D.M S of the division, who controls the field ambulances, dressing stations, aid posts, and sanitary sections in the divisional area.
>
> To show exactly how these formations work, it will be as well to trace the normal progress to the rear of a man who has been struck down in the firing line. Wounded while advancing, he has possibly been left lying in the open under a hail of shrapnel bullets which are striking the ground all round. From this hazardous position he is rescued by two stretcher bearers, who, choosing their moment, rush across, pick him up, and carry him back to the shelter of a trench. These bearers may either be from his own unit—16 men of which in the case of an infantry battalion have been trained in first aid and stretcher drill—or they may be men of the Royal Army Medical Corps belonging to a bearer subdivision of a field ambulance. They will take him to his "regimental aid post," probably situated in a dug-out, in a cellar, or in some sheltered spot giving cover from fire, where he will receive first aid from the R.A.M.C. officer attached to the battalion. From there he will be conveyed either on a stretcher or, if circumstances permit and a road is handy, in a horsed ambulance wagon to the nearest dressing station.

Divisional Field Ambulances.

The wounded man now passes into the charge of the divisional field ambulances, the bearer subdivisions of which collect the wounded, while the tent subdivisions form dressing stations. At the dressing stations, which are pushed as near as possible to the front, his wound is attended to and he is injected with antitetanic serum. He is then removed by motor or horsed wagon to a larger dressing station further to the rear, where he must remain for some time during the process of sorting the wounded, but where he receives food and drink and is made as comfortable as the circumstances allow. He is now prepared for transport to the

Casualty Clearing Station.

> So soon as he is placed on a motor ambulance wagon (says "Eye-Witness") belonging to a detachment of the Motor Ambulance Convoy and starts on the next stage of his journey he passes out of the hands of the division into the formations which are under the direct control of the army. These motor convoys, the first units of the kind that have ever been used in war, each consist of a large number of vehicles, with the necessary officers and other ranks. A proportion of these units are allotted to each army. The Casualty Clearing Stations, to one of which the wounded man is now brought, are under existing conditions generally situated at the railheads, so that patients can be carried direct from them to the ambulance trains, though this would not always be the case in field warfare; for instance, where troops were advancing every day. Their position, however, is always chosen with a view to facilitate despatch by ambulance or train. They are not hospitals in the true sense of the word; but a proportion of serious cases, such as those of certain kinds of injury to the head or abdomen, which cannot be moved without danger, may be retained in them for a considerable time. Although equipped and staffed to deal normally with 200 patients, they have a sufficiently elastic organisation to be able, if necessary, to cope with much larger numbers during the progress of a battle, and special arrangements are made for temporarily augmenting the staff when severe pressure is expected.

"Eye-Witness" mentions here that during the operations at Neuve Chapelle one clearing station admitted on an average nearly 800 wounded daily for four consecutive days, passing 3653 cases to the base in six days. At the clearing station, where nursing sisters and beds first appear on the scene, the length of stay is determined partly, as has been mentioned, by the nature of the wound, but mainly by the railway facilities. Once on board the train the patient leaves the "collecting zone" and enters the "evacuating zone."

Ambulance Trains.

"Eye-Witness" continues:—

> There are 14 ambulance trains now running. Each has a personnel of 3 officers and 47 other ranks of the Royal Army Medical Corps, and 3 nursing sisters. The number of wounded conveyed on any journey depends on the nature of the injuries—i.e., whether the sitting-up or lying-down cases predominate. With the exception of certain specially designed trains, which have been built by some of the great railway companies in England, the rolling stock is made up of various kinds of coaches and "fourgons" belonging to the French railways, which have been adapted for the accommodation of wounded, staff, kitchens, dispensaries, and stores. The number of trains will eventually be made up to 24, the coaches for the additional units required being now under construction in England, or already in transit to France. Several of these trains have been presented to the nation by private donors.

On arrival at a base the wounded man is carried by motor ambulance to a permanent hospital.

Permanent Hospitals.

> These hospitals are of two kinds, says "Eye-Witness"—general and stationary—the difference between the two lying chiefly in the number of patients they are designed to accommodate. The first are the largest and are elaborately equipped, being fitted with all the modern appliances of the first-class hospitals met with in civil communities. Stationary hospitals are not necessarily situated at a base, but may be located at different points on the lines of communication, and, in spite of their title, are intended to be more mobile than the general hospitals.

A third category of hospitals found at the bases is composed of Red Cross or voluntary hospitals. The personnel and equipment of these are provided by the society or subscribers who organised the unit, but each is under the command of an officer of the Royal Army Medical Corps. These establishments vary in capacity. Some are directly provided by the British Red Cross Society, and others work under its auspices. The remainder are the Australian Voluntary Hospital, which was the first of its class to land in France during the early part of the war, and the Liverpool Merchants' Hospital, which has only quite recently arrived. The Allied Forces Base Hospital, which has rendered useful service, has been temporarily closed, but will reopen at an early date.

All the base hospitals are established in huts, tents, or in buildings suitable for the purpose, such as hotels or casinos. The duration of the patient's sojourn in one varies directly with the nature of his wound. Very severe cases, which it would he inexpedient to move, and slight cases likely to be fit for duty or discharge to a convalescent camp within three weeks are retained. Those which are unlikely to recover within three weeks, and will not be harmed by further transport—and by far the largest number comes within this category—are sent to England so soon as accommodation is available on board a hospital ship.

"Eye-Witness" concludes his bird's-eye view of the medical work at the front by pointing out that it is founded on two leading principles: the maintenance of the mobility of the army by relieving the fighting troops quickly of non-effectives; and secondly, the rapid removal of the sick and wounded to places where they can be treated in the most favourable conditions. The arrangements for the evacuation of the sick and wounded along lines of communication, which are also required for the bringing up of food and ammunition, necessarily require a high degree of organisation. By pointing out that, inasmuch as nothing can be allowed to interfere with the needs of the fighting troops, the care of the wounded will now and again depend upon circumstances out of the control of the Army Medical Service, "Eye-Witness" answers in a sentence a great deal of ill-informed criticism.

How general the feeling is that the Royal Army Medical Corps has highly distinguished itself during the war is shown by the statement that "Amongst the many and diverse duties which fall upon the Royal Army Medical Corps during war perhaps none present more intricate problems than those which arise in connexion with the evacuation of wounded. And it is safe to say that during the present campaign none have been performed with greater efficiency, often in the face of immense difficulties imposed by the nature of the military operations."

He concludes by alluding to the conveyance of the wounded by barges, a method which has been employed in Northern France for the evacuation from Casualty Clearing Stations of seriously wounded men. The lives of such men might have been endangered by the jolting associated with train or motor journeys, and many critical cases have been carried by barge from the neighbourhood of the front to hospitals on the lines of communication, the barges having been specially converted into hospital craft and fitted with operating tables and necessary accessories.

ITALY AND THE WAR: ADDRESS BY PROFESSOR BACCELLI.

While the "Third Italy" was unveiling the memorial in marble on the Genoese seaboard, whence Garibaldi and his "thousand" embarked for the emancipation of the two Sicilies, she was at the same hour (writes an Italian correspondent) bidding Godspeed to her medical youth on the mission reserved for them in the consummation of her unity. The eloquence of D'Annunzio before the one assembly had its echo in the glowing words of Guido Baccelli before the other—words addressed to the Roman students at the close of the Medicus Annus in the Policlinico—Baccelli's own creation.

Baccelli's theme was the "Medico Soldato," and in developing it he expatiated on the whole field of medicine in its relation to war, starting from the Hellenic foretime, when the death of Machaon, the surgeon-general of the Greek army before Troy, shed dismay throughout the camp, down to the second decade of last century, when the great Napoleon pronounced his monumental *éloge* on Baron Larrey, the head of the medico-military staff. The Emperor's tribute to the service of that staff in maintaining the moral as well as the physical efficiency of his troops inspired the Roman physician to a luminous illustration of what the medical art can achieve under the far more complicated and difficult conditions of twentieth century warfare, winding up with authentic instances of such achievement drawn from Italy's recent annals, in which the regimental surgeon under fire, after exhausting the resources of his *métier* in tending the wounded, had himself to become a soldier, and by his prowess and skill in the fighting line, against overwhelming numbers, aided his combatant compatriots to retrieve the day when seemingly lost. Very significant in the present phase of what Italians call this "inhuman contra-human war," was Baccelli's allusion to Rome's victories over her barbarous enemies beyond the Alps, victories culminating in the triumphs recorded on the Antonine Column, in words still legible—

> Marcus Aurelius Imperator
> Armenis parthis *Germanisque*
> Bello maximo devictis
> Triumphalem hanc columnam
> Rebus gestis insignem
> Antonino Pio patri dedicavit.

In connexion with this allusion Baccelli recalled as a "historical incident," the request made to him by the Kaiser Wilhelm for a description of the habiliments of the Marcomanni, as engraved on the column when these were prisoners of war at the hands of the Roman legions. From this digression the orator proceeded to show how, if the military art can devise her methods of inflicting wounds and extinguishing life, the medical art is not behindhand in coping with these. Over and above the superior sanitary conditions in which the soldier lives in camp or quarters, the advance in medicaments and the means of introducing them into the system is not less conspicuous, as illustrated by the largely extended and reinforced "armamentarium chirurgicum" and the methods of treating what, for instance, used to be an "opprobrium" of military surgery—tetanus. Amplifying this thesis with illustrations from his own clinique, particularly in the field of intravenous injection, Baccelli paid a glowing tribute to the work of all the belligerent nations now at war, and drew from it the hopeful, the reassuring, augury that the humanely inspired function of the healing art will one day react in a moral sense on the destructive instincts still present in man, pressing home the conviction that civilisation has nobler ends to aim at and to achieve than those of international jealousy and antagonism, and that the forces now at deadly variance may yet be reconciled to coöperation in unison against the perennial adversary, insanitation and disease.

Quod felix faustumque sit was the aspiration evoked by this humanitarian forecast from the crowded audience, professional and lay, that hailed with successive salvoes of applause the veteran orator as he resumed his seat.

TYPHUS FEVER IN PRISONERS' CAMPS IN GERMANY.

The United States Ambassador in Berlin has warned the British Foreign Office through the United States Ambassador in London that typhus fever has broken out in the following prisoners' camps in Germany:—

Altdamm.
Cassel.
Chemnitz.
Gardelegen.
Langensalza.
Sagan.
Schneidermuhl.
Wittenberg.
Zerbst.
Zossen.

Letters will not be despatched from these camps owing to the risk of transmitting the disease.

THE DENTAL NEEDS OF THE ARMY.

That more dental surgeons should be attached to the Expeditionary Force has been the opinion of a good many observers. A vast amount of dental work is waiting to be done. This will cause no surprise to those acquainted with the dental conditions of this country, and more especially to those who have had the opportunity of seeing the condition of the mouths of those accepted as recruits. Man after man has been returned from France suffering from conditions traceable to the teeth, conditions which could easily have been avoided by a little foresight. It is known that during the Boer War nearly 2500 soldiers were invalided home from South Africa on account of teeth, and it has been computed that this meant a financial loss of nearly a quarter of a million to the nation. Yet the lesson was not learnt, and no adequate steps were taken.

On the outbreak of the present war there was no machinery for dealing with this serious question of dental disease in the soldiers, and the work of attempting to deal with it devolved mainly on the philanthropy of the dental hospitals and of private practitioners, and to their credit be it said that they did all that was possible. Subsequently, during September and October, about 12 dental surgeons were sent to France, and since then others have gradually been appointed to various centres. The number appointed is, however, quite inadequate to deal with the extraordinary amount of dental disease, and reliance has still to be placed on the charitable institutions which in many instances have, we believe, entered into business arrangements with the War Office. The provision made is still inadequate and in many ways most unsatisfactory. In the first place, dentistry, although a branch of medicine, requires special knowledge, and it would therefore seem advisable that for this section of the army medical work the Director-General of the Army Medical Service should be able to call for the best expert aid in general organisation. In the second place, the work which is being done by the various officials of dental hospitals and by dental surgeons attached to the general hospitals is not officially recognised. In many cases these officials are medical men, and it would be more satisfactory if they were accorded rank as it is accorded to other civilian medical men employed on war service. The absence of proper recognition of the workers makes it extremely difficult to obtain the service of the younger men. To our knowledge there has been a great trouble in persuading young dentists that they are doing better work by remaining at home and attending to the dental needs of the soldiers than by joining the forces as combatants.

At the recent meeting of the Edinburgh Dental Hospital Lieutenant-Colonel Sir Joseph Fayrer, colonel in command at Craigleith Military Hospital, referred to the want of a properly organised Army Dental Department, and hoped that at every examination of the Royal Army Medical Corps there would be vacancies for dental surgeons who should also be qualified otherwise; we presume he meant medically qualified. There is much in this suggestion. The army dental surgeon does not need to be an expert in dental mechanics, but rather one capable of performing surgical operations on the teeth, knowledge which a medical man can acquire in a period of possibly six months. It is quite clear that the near future will see a demand for dental surgeons for the naval, military, and civil services; such men will not require the elaborate mechanical training now demanded by the various licensing bodies, rather will these dental surgeons be required to possess a good knowledge of allied medical conditions, so as to give them a basis for forming general conclusions. We think that those responsible for dental education should seriously consider the question and make the curriculum of the dental students less mechanical and more medical in its character.

THE Metropolitan Counties Branch of the British Medical Association have appointed a War Emergency Committee, and a circular has been sent to the members asking them to fill up and return a form indicating their ability to offer to the War Office whole-time or part-time service.

THE KING GEORGE HOSPITAL.—The working of the dental department of the King George Hospital has now been arranged so that one of the honorary dental surgeons will be in attendance on each morning of the week. Each dental surgeon has strengthened his department by the appointment (with the approval of the committee of management of the hospital) of a qualified clinical assistant, and he has, moreover, been specially provided with an anæsthetist. In this way the work of the dental department ought to be carried on with equal smoothness and efficiency.

The three rooms which have been set aside for the dental work are upon the top floor (the fifth) of the hospital, and are provided with large windows with a north aspect. In the afternoon these same rooms will be at the disposal of the surgeons who are in charge of the laryngeal and aural cases. Apparently, it has not yet been decided if qualified clinical assistants will be called for in connexion with these cases; but inasmuch as a great deal of important operative work will be taking place such appointments might prove of great value and importance, whilst the ordinary resident medical officer can hardly be expected to possess that special knowledge which might be desirable.

THE SCOTTISH WOMEN'S HOSPITALS.—The scope, character, and services of the Scottish Women's Hospitals were well explained by Dr. A. Louise McIlroy recently to a meeting at Airdrie, near Glasgow. Dr. McIlroy referred to the objections that had been promulgated against the Scottish Women's Hospital scheme. To the charge that it was competing with the Red Cross Hospitals it was replied that the British Red Cross was occupied in the service of our own troops, who were the best looked after troops in the world, while the women's hospitals were devoting their attention to our Allies. The Red Cross itself had materially assisted them and there was no overlapping. As to the expressions of apprehension concerning the fitness of women doctors to engage in such strenuous and arduous work and to undertake the very grave operations, Dr. McIlroy said that at first the British War Office would not employ women, so one little band of women doctors had gone out on their own account, and had done so well among the soldiers that they were taken on to Boulogne. They had since come back to London, where the War Office had given them a hospital of 500 beds to look after, staffed entirely by women. Dr. McIlroy described the hospitals of the Scottish women, which were divided up into units of 100 beds, with a fully equipped staff of women doctors, nurses, X ray apparatus, and laboratories on as complete a scale as the large infirmaries at home. The efficiency of all this equipment had been absolutely dependent on the generosity of the Scottish people. Dr. McIlroy contrasted the system and provision in Flanders and France, where they were remarkably well provided for and attended to, with that in Serbia, where they had to deal with, not only the wounded, but small-pox, diphtheria, and, it was said, plague, which was beginning to appear in some parts of Southern Europe. More than half of the Serbian doctors had died from typhus fever, and daily 10, 15, and 20 patients were dying. The great need of Serbia was more doctors and trained nurses, especially those with experience in fevers. They were now providing fully equipped tents and marquees as hospitals. They were fighting the disease that would follow the war, which it was their duty to keep from spreading to the other side of Europe.

ZEPPELINS IN THE MOUTH OF THE THAMES.—Southend-on-Sea was visited by Zeppelins just before day-break on Monday morning, and about 100 bombs, mostly of an incendiary character, were dropped on the town and its outskirts. Outbreaks of fire occurred in five or six places, and damage estimated at £20,000 was done. One woman unfortunately lost her life, a bomb coming through the roof just over the bed in which she was lying asleep with her husband. The husband escaped with considerable injuries about the head and neck. One of the houses which was partly burnt out was that of Mr. H. W. Hull, a local medical practitioner, who is at present serving in the Royal Navy as surgeon on a hospital ship in the North Sea. He happened to be at home on 48 hours' leave of absence, and was awakened to find his house on fire.

RUSSIAN VITAL STATISTICS.—The Russian *Government Gazette* has just made a statement with regard to the organisation of medical aid in Russia, based on published information from the Chief Medical Inspector. The figures do not deal with a later date than the end of 1912, but allow us, none the less, to gauge to some extent the national health of our great ally. The vast size of Russia, as well as the backwardness of enormous districts of the empire, accounts for the impossibility of acquiring and publishing more recent figures. The mortality in Russia fell in 1912 to 25·9 per 1000, or 3·2 per 1000 lower than the average mortality of the preceding 10 years 1902–1911. The birth-rate, which was 43 per 1000, was 2·5 per 1000 lower than the average of the preceding 10 years. The natural increase of the population was 17·1, or 0·7 per mille more than the average of the period named.

The mortality from infectious diseases in European Russia declined considerably in 1912, amounting to 397 per 100,000 of the population, whilst in the preceding year it was 467, and in 1910 635. Similarly there was a great decline in the cases of infectious diseases excepting measles and whooping-cough. Of the total number of cases of sickness registered 67 per cent. consulted doctors, and 33 per cent. assistants, who are recognized in Russia as a lower order of practitioners. 18·4 per cent. of the diseases registered referred to the alimentary canal; infectious cases accounted for 16·3 per cent.

The statistics concerning the medical profession are very interesting, as they indicate that the difficulty of finding medical officers for the Russian army may have been considerable. The members of the civilian medical profession at the end of 1912 numbered 22,772, plus 28,500 assistants, 14,194 maternity assistants, 7238 dental surgeons and dentists. And the number of pharmacists was 13,357. Of the medical men, 72 per cent. were in the towns and 28 per cent. in the rural communities. There was one medical man to 1450 people in the towns, but only one to 21,600 in the country. The average number of inhabitants in the empire per doctor was 7200—viz., 6500 in European Russia and 13,100 in Asiatic Russia.

The number of hospitals and refuges was 8110, with 219,978 beds, of which 171,514 were in general hospitals. There were 41,404 beds in psychiatric hospitals and 7060 in lying-in establishments. In all the hospitals there were 3,311,637 cases during 1912, of which 162,446, or 4·9 per cent., were fatal. The deaths in hospital made 3·8 per cent. of the total in the Empire. In the psychiatric institutions there were 92,989 cases, with a mortality of 9·2 per cent. In the lying-in houses and refuges there were 309,626 cases. The number of births was 256,374, or 3·6 per cent., of the total births in the empire; the mortality was 0·4 per cent. At 28 Pasteur institutions 37,935 subjects were treated, and the deaths numbered only 136.

VACANCIES FOR MEDICAL OFFICERS.—Three medical officers are urgently required to complete the establishment of the 2/1st Highland Mounted Brigade Field Ambulance. Particulars of duty, pay, &c., will be given on application to the Officer Commanding, 2/1st Highland Mounted Brigade Field Ambulance, R.A.M.C., Houghton Hill House, Houghton, Huntingdon.

WOUNDED ALLIES RELIEF COMMITTEE.—Dr. Isabel Ormiston, chief medical inspector of schools to the Government of Tasmania, and Mrs. Patton Bethune, who were sent as a Sanitary Commission to Montenegro, have arrived at Cettigne and report that the Montenegrin Government request the despatch of a self-supporting hospital unit and a supply of vaccines, as well as disinfectants, to combat the typhus epidemic in Ipek and the surrounding country. The committee is proceeding to equip a suitable unit.

The Belgian Army Medical Commission has requested the Committee to undertake the care of a number of tuberculous Belgian soldiers who have acquired the disease during the hardships endured last winter in the trenches. The Committee appeals urgently for premises in which to establish a home. If any owner of a house on high ground and at the seaside would be so generous as to lend it for this purpose particulars will be gratefully received by Mr. Albert Van der Velde, honorary hospital superintendent, Wounded Allies Relief Committee, Sardinia House, Kingsway, W.C.

A MOTOR-CAR VOLUNTEER CORPS IN EDINBURGH.—A meeting of motor-car owners was held on May 10th in the North British Station Hotel, Edinburgh, to consider the question of forming an Edinburgh section of the National Motor Volunteer Corps. Mr. W. L. Sleigh, who had been invited by the headquarters of the force to form a local section, explained that the principal objects of the body were to provide local assistance to the regular army transport in the event of attack, assistance to recruiting officers and officers visiting lines of communications, hospital and Red Cross work, &c. He stated that the services of the force had been regularly used by the War Office in districts where companies were organised, and that it was desired to have local centres formed so that the provinces should be linked together. Following the discussion of the proposal the meeting resolved to form an Edinburgh section of the force, and further resolved itself into a committee to obtain members. A subcommittee, consisting of Bailie Rusk, Mr. Sleigh, and Mr. J. Scott Law, were appointed to make arrangements for the proper organisation of the movement.

THE BRITISH HOSPITAL AT PORT SAID.—At all times the provision of adequate hospital accommodation at Port Said, that gate between the East and West, is an object of great importance, but it is easy to understand that it becomes an imperative necessity for our wounded soldiers and sailors in the Near East at the present time. The hospital is now making an urgent appeal for £10,000 for its completion and equipment, and those who wish to contribute may address themselves to Mr. Arthur Stanley, M.P., London Chamber of Commerce, 1 and 2, Oxford-court, Cannon-street, E.C.

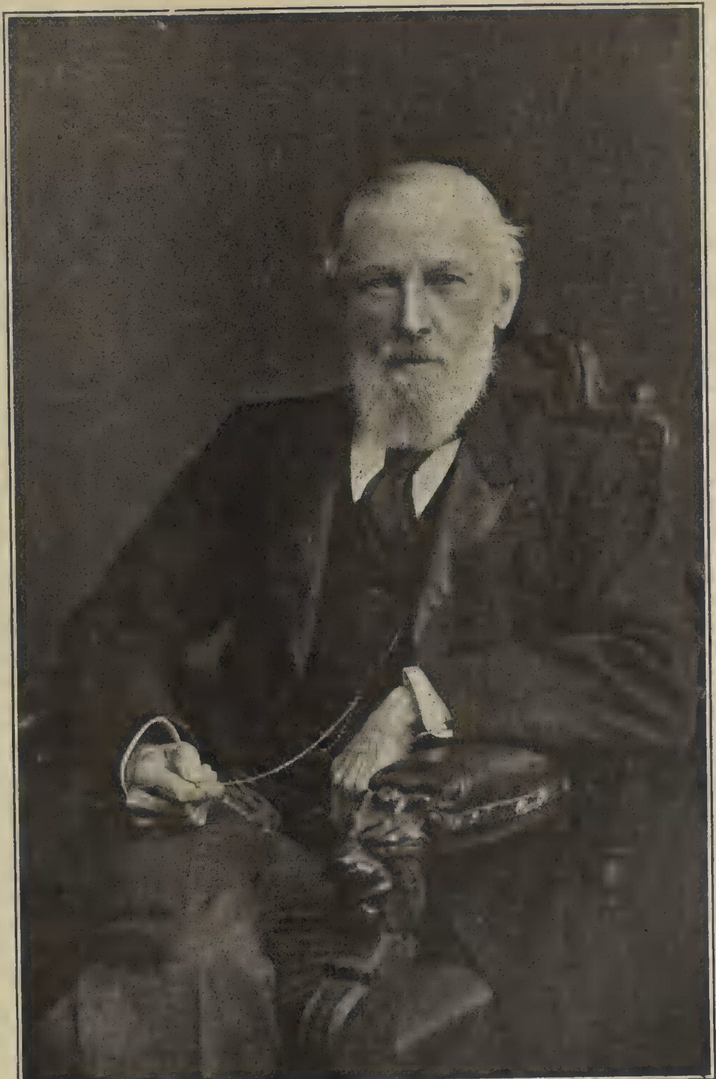
THE BELGIAN FIELD HOSPITAL.—Mr. H. W. Morrison has been appointed commandant of the Belgian Field Hospital, in succession to Mr. W. S. Perrin.

Obituary.

SIR WILLIAM RICHARD GOWERS, M.D. LOND. AND DUB., F.R.C.P. LOND., LL.D. EDIN., F.R.S.,

CONSULTING PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL, LONDON, AND TO THE NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN-SQUARE, W.C.

William Richard Gowers was born on March 20th, 1845, and was educated at Christ Church College School, Oxford, and at University College Hospital, London. He was apprenticed for some time to Dr. Simpson, a practitioner in Essex. He had a brilliant career at his hospital and at the University of London. He qualified M.R.C.S. in 1867, took his M.B. degree in 1869, and his M.D. in 1870, winning the gold medal in that year. In 1879 he was elected a Fellow of the Royal College of Physicians of London, and was appointed Goulstonian lecturer, taking as his subject "Epilepsy." In these lectures he embodied the results of a careful, methodical, and laborious investigation of 1450 cases of epilepsy, and the volume containing the substance of the lectures, published a year later, remains still one of the classical works on this subject. A second edition, embodying the results of observations on over 1500 additional cases, 3000 in all, was published in 1901. He was elected to the staff of University College Hospital and of the National Hospital for Paralysis and Epilepsy. He had previously acted as registrar at the latter institution. Although his early work was on diseases of the heart and blood, on which subject he contributed articles to Reynolds's "System," he had already been attracted to the study of nervous disease, and he made his great reputation chiefly on account of his work on these diseases. During the first part of his time at University College Hospital he was closely associated with Sir William Jenner, for whose character and abilities he always retained an almost reverent admiration. He was also for many years on terms of almost affectionate intimacy with his relative, Sir John Russell Reynolds, and these two masters of clinical medicine counted for much in his methods of work.



SIR WILLIAM R. GOWERS, F.R.S.

It is difficult now to realise the state of chaos in which the knowledge of nervous diseases, especially as regards pathology, was at the time Gowers began to work at them, and it is in great degree due to the extraordinary character of his work in investigating and systematising that our knowledge of these diseases is now perhaps more complete than of any other branch of medical science. The first great step in this systematisation was a lecture which he published in 1879 on the Diagnosis of Diseases of the Spinal Cord. This lecture, afterwards published as a separate volume, attracted much attention at the time. It was illustrated by the representation of a series of sections of the spinal cord, in one of which was represented the area of ascending degeneration which Bechterew subsequently described and named "Gowers's tract." But the lecture was really epoch-making because of the manner in which pathological anatomy and clinical symptomatology were brought into relation, and it laid the foundation of the wonderfully complete knowledge which we now possess of the organic diseases of the spinal cord. His volume on "Medical Ophthalmoscopy" was published soon afterwards and was of inestimable value and interest.

In 1885 Dr. Gowers published a volume on "Diagnosis of Diseases of the Brain." By this time the clinical and pathological observations of Hughlings Jackson, and the experimental work of Fritsch, Hitzig, and Ferrier had completely altered the conceptions of cerebral physiology and function, and Gowers's acute mind readily grasped the significance of their observations. In the volume referred to, which consists of 18 lectures, principles were laid down and rules enunciated which at the present day are perhaps a little extended but scarcely in any way altered. This book will remain for many years an indispensable part of every neurologist's library.

It would be impossible to enumerate all the articles which in this and in preceding years, and to a less extent in subsequent years, seemed to pour from Gowers's pen. We need only mention such articles as those on pseudohypertrophic paralysis, on canine chorea, on hydrophobia, and on many other subjects. These, admirable and valuable in themselves, were only facets, so to speak, of the great work on which he was engaged—the "Manual of Diseases of the Nervous System." The first volume of this, on Spinal Cord Diseases, was published in 1886; the second, on Diseases of the Brain and Functional Disease, in 1888. With the publication of the first of these volumes the author stepped at once into the very first rank of neurologists, and on its completion the great value of the work was recognised both in America and in Europe. It was reprinted in the United States, and it was translated into German, Italian, and Spanish. Second and third editions of the first volume were subsequently published; a second edition also of the second volume appeared. A third edition of the second volume, which was in contemplation, was never completed. Gowers also had it in his mind to cut down the "Manual" to one volume by omitting the anatomical and physiological parts. There is little doubt that this would have made an exceedingly useful clinical manual of nervous diseases, and one cannot but regret that it was never completed. In 1892 he also published his Lettsomian lectures on Syphilis of the Nervous System, delivered three years earlier.

The immense work which all the above publications involved, coupled with the anxieties of a large practice, unfortunately led to a breakdown in Sir William Gowers's health, which had never been very robust. This necessitated a voyage to South Africa, from which he returned much improved. In spite of the engrossing claims of his practice he continued to publish much useful matter. His Bradshaw lecture on Subjective Sensations of Sound, given before the Royal College of Physicians of London, and his Bowman lecture on Subjective Sensations of Sight, given before the Ophthalmological Society of the United Kingdom, are both valuable for the investigations and observations described in them, and suggestive because of the conclusions drawn from them, and a small volume on the "Borderland of Epilepsy" contains much that is interesting and useful. It has been translated into German. Several volumes of clinical lectures have also been published.

We are still too near the epoch in neurology so closely associated with the work of Gowers to estimate properly his position in it. Yet the scientific advances in that department of medicine have been so great and rapid as to make it easier perhaps to appreciate his great work without the danger of over-estimating its importance. It may be stated without fear of contradiction that Gowers was an extraordinary observer, accurate and painstaking, with a wide horizon and a sound judgment which made his deductions from observations both definite and reliable. He had a marvellous power of what might be called intensive deduction. He was a rapid reader and worker, and could crystallise the gist of much reading in a very few sentences. He had great capacity for work, and although he was not always an easy man to work with (for he did not "suffer fools gladly") yet no one was more appreciative of help and assistance than he was. His position in neurology was unique, because he was a great observer and a still greater expounder. His teaching power was remarkable, and to his out-patient afternoons at the National Hospital in Queen-square in the "eighties" must be traced in large degree the deservedly high reputation which that hospital enjoys as the chief centre of neurological teaching in this country at the present time. And in his publications, especially in his "Manual," this extraordinary power of assimilation of knowledge from all quarters, always enriching, sometimes modifying his own observations, together with the faculty of setting it all out in clear and graphic language, is peculiarly striking. The late Dr. Hughlings Jackson often remarked that he would always be grateful to Gowers because of the manner in which Gowers had expounded the Jacksonian theories. Yet if Gowers had not been the wonderful teacher and expounder that he was he would have been recognised as a great investigator and observer.

He was the recipient of many honours. He was elected a Fellow of the Royal Society. He received the Hon. M.D. of Dublin and was elected an honorary Fellow of the Royal College of Physicians of Ireland; he was an honorary member of the American Neurological Association, of the Netherlands Society of Psychiatry and Neurology, of the Russian Society of Medicine, of the Royal Society of Science of Upsala, of the Society of International Medicine of Vienna, and he was LL.D. of the University of Edinburgh. He received the honour of knighthood in 1897.

It might well be thought that a man who was responsible for so much medical work had no time to indulge in hobbies. But Gowers was a diligent and skilful etcher, devoting much of his holiday time to this art. His work, some of which has been exhibited at the Royal Academy, is characterised by artistic feeling as well as by technical skill. He was also much interested in mosses, and his knowledge of them was extensive and minute. Indeed, it may be said that all aspects of nature held a strong appeal for him. The beauties of nature were a constant joy to him, and it is interesting to know that from early days he was a devoted admirer of Ruskin and a constant student of his works. He was an enthusiastic advocate of the use of shorthand, and himself an excellent stenographer, using shorthand for all his notes both of hospital and private patients.

Sir William Gowers married the daughter of Mr. Frederick Baines, of Leeds. She died in 1913, leaving four children—two sons and two daughters. It may be mentioned without impertinence that Sir William Gowers was peculiarly happy in his married life and a devoted husband and father.

JAMES MILLEN MOORE, L.R.C.P. & S. EDIN.—Great regret has been caused in Lurgan and the surrounding district by the sudden death on April 25th, at his residence in Lurgan, of a well-known practitioner, Mr. J. M. Moore. Mr. Moore, who was 68 years of age, had attended service in the parish church of Lurgan in the morning, but later in the day, while walking in his garden, he was suddenly taken ill. Making his way to his house, he was in the act of drinking a glass of water when he fell to the floor and died in a few minutes from cardiac failure, in the presence of two of his medical friends, who had been hastily summoned. A native of Dungiven, co. Londonderry, where his father and several of his brothers practised, he studied at Foyle College, Londonderry, and at Queen's College, Belfast, and in 1868 he became L.R.C.P. & S. of Edinburgh. After assisting his father for a time, Mr. Moore settled in Lurgan, where he built up a large working-class practice. He also took a prominent part in the business and educational affairs of Lurgan. He is survived by an only son, his wife having pre-deceased him some years ago.

DEATH OF LIEUTENANT-COLONEL ROBERT MARK BRADFORD, A.M.S. (RETIRED).—Lieutenant-Colonel R. M. Bradford died recently at his residence, Bradford Peverell, near Dorchester. He was the son of the late Rev. J. Bradford, formerly vicar of Pinhoe, Devon, and received his medical education at St. Bartholomew's Hospital. He qualified as L.R.C.P. Edin. and M.R.C.S. Eng. in 1868, and shortly afterwards entered the Army Medical Service. On his retirement he took up his residence at Bradford Peverell, where he was highly esteemed. He was on the committee of the Dorset County Hospital and was secretary of the Dorset Orchestral Association.

DEATH OF PROFESSOR G. HEINRICIUS.—Professor Heinricius, who held the chair of midwifery and diseases of children in the University of Helsingfors, died recently, at the age of 62 years.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE Fund has received in the last fortnight some large additions; these, however, have not been the result of recent subscriptions, but represent the paying to the treasurer of money collected over a considerable range of time by local funds. A splendid donation from the Canadian Committee brings the contributions from this source to nearly £1500.

The money in the hands of the Executive Committee is sufficient for immediate wants, as will have been gathered from the weekly reports in the medical and pharmaceutical press, but it is most important to understand that the calls upon the Fund in the future will be heavy.

THE LIVERPOOL FUND.

At a recent meeting of the committee formed under the auspices of the Liverpool Medical Institution it was resolved to remit £400 to the treasurer, Dr. H. A. Des Vœux. The Liverpool Fund still remains open, and attention may be drawn here to the fact that a considerable number of the medical profession in Liverpool and district, as well as of the members of the Liverpool Medical Institution, have not yet sent in their subscriptions. These will be gratefully welcomed by the local honorary treasurer, Dr. T. R. Bradshaw. The following list is the third; the first and second were published in THE LANCET of Jan. 23rd and Feb. 13th respectively.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments kindly contributed by the following donors since the publication of the last list:—

Miss C. W. Hyde, Southampton; Dr. C. W. Buckley, Brixton; Mr. A. Broomhall, Hull (per the Voluntary Aid Committee); and Mrs. C. J. Kayser, Fleet.

Medical News.

Royal College of Surgeons of England.—At the First Professional Examination for the Licence in Dental Surgery on April 29th and 30th the following candidates were approved in the undermentioned subjects :—

Mechanical Dentistry and Dental Metallurgy.—Leslie Douglas Crabb, Edward Tong Crosoer, Richard John Gustavus Handel, and John Herbert, Guy's Hospital; Frank Hiam, Royal Dental Hospital; William Trevor Johnson, Birmingham University; Clifford Andrew Loveluck, Philip Henry Marsh, and William Mercer, Guy's Hospital; Ernest George Parkinson, Manchester University; Herbert Alfred Potter, Royal Dental Hospital; Harold John Powell and Bertie Moorwood Tonkin, Guy's Hospital; and Frederick Charles Truman and Ernest Arthur West, Birmingham University.

Mechanical Dentistry.—Albert William Ewart Chapple, Manchester University; William Ashley Cooper, Birmingham University and Guy's Hospital; Alfred Innes Cox, Royal Dental Hospital; Edmund Percy Deverall, Jenkin Albert Evans, and George Frederick Faustmann, Guy's Hospital; William Grant Milton, Bristol University; Johann Lodewijk te Water Naudé, Royal Dental Hospital; Arthur Arnold Osman, Guy's Hospital; Robert Wolff, Royal Dental Hospital; Walter Reginald Wotton, Guy's Hospital; and Malcolm Wykes, Birmingham University.

Dental Metallurgy.—Douglas William Smale Adams, Guy's Hospital; Harold John Allen, National Dental Hospital; Hubert John Vere Raywood Allin, Birmingham University; William Blair Spence Andrew, Royal Dental Hospital; Victor Henry Ball, London Hospital; John Laurence Barber, Liverpool University; Cyril Arthur Duvall Bishop, Guy's Hospital; Hubert Bruckmann, Royal Dental Hospital; Alfred Joseph Chiappa, National Dental Hospital; Eric Norman Commander, Birmingham University; Bertram Poole Cousins, Guy's Hospital; Thomas John Davies, London Hospital; Harold James Dawes, B.A. Cantab., Birmingham University; Pieter Jacob Stephanus de Wet and Hyman Fox, Guy's Hospital; Edwin Stowell Gawne, Liverpool University; Ralph Byron Gibson, Sheffield University; Lacy Norman Glaisby, Royal Dental Hospital; Edwin Spencer Goodwin and Philippus Elisa Grobbelaar, Guy's Hospital; Arthur Robert Hill, Royal Dental Hospital; John Christopher Johnson, Hugh Llywelyn Jones, Roy Victor Kingham, and Felix Reginald Knowler, Guy's Hospital; Frank Lawrence, London Hospital; John Leslie Lean, Guy's Hospital; Georges Maes, Brussels and Royal Dental Hospital; Harihar Gangadhar Moghe, L.M.S. Bombay, Bombay and National Dental Hospital; Edward Alfred Penney Parker, Guy's Hospital; Withiel Herbert Leslie Phillips, Birmingham University; Richard Stanislaus Roche and Ernest Findlay Shaw, Guy's Hospital; Cyril Fryer Smith, Liverpool University; and Herbert Victor Vogt, Albert Weinberg, George Wilshere, Thomas Alexander Moffat Wilson, D.M.D. Harvard, and William Adam Woodward, Guy's Hospital.

Apothecaries' Hall of Ireland.—The next examination for candidates seeking the licence in medicine, surgery, midwifery, and pharmacy will begin as follows :—Primary Examination, Monday, June 7th; Intermediate, Part I., Monday, June 14th; Intermediate, Part II., Monday, June 21st; and Final Examination, Monday, June 28th.

Bristol Children's Hospital.—The annual meeting of the Ladies' Auxiliary in connexion with this hospital was held recently under the presidency of the Duchess of Beaufort. The report showed that during 1914 38,000 houses had been canvassed, with the result that the sum of £1023 was raised for the funds of the institution. This is the largest amount collected in any year by the Ladies' Auxiliary.

Pharmacists and the Medical Curriculum.—The secretary of the Pharmaceutical Society has written to the Registrar of the General Medical Council to inquire whether, in view of the shortage of medical men, the Council would be prepared to consider favourably the suggestion that duly qualified pharmacists who desire to enter upon the medical curriculum might be excused the medical preliminary examination and such parts of the qualifying examination as are included in the subjects which the pharmacist has to pass in order to qualify under the Pharmacy Acts.

Leicester Royal Infirmary.—The number of in-patients received by this hospital, as shown by the 142nd annual report for the year 1914, was greater than that recorded in any previous year—namely, 4003. The average number of beds occupied during the year was 250·9. The total number of attendances in the out-patient department was 35,091, made up of 10,910 new cases, 22,034 old cases, and 2147 cases remaining on the books on Jan. 1st. It is satisfactory to note that the income has about equalled the expenditure, while the whole of the sources of income have been well maintained. For the building and equipment of a new pathological department a sum of £1800 has been promised, leaving a sum of £2400 to be obtained. With reference to the reconstruction of the Children's Hospital, which has resulted in the improved health both of patients and nurses, it is pointed out that a debt of £2200 remains to be liquidated, and the board hope that the hospital may be placed on the list of all subscribers to the infirmary for annual subscriptions and contributions.

The annual general meeting of the Asylum Workers' Association will be held at 11, Chandos-street, Cavendish-square, W., on Wednesday next, May 19th. The chair will be taken at 3 p.m. by Sir John Jardine, K.C.I.E., M.P., LL.D., president of the association. The annual report will be submitted, officers elected, and presentations will be made of medals for long and meritorious nursing service. Matters of much importance to asylum workers will be discussed, and it is hoped that there will be a large and representative gathering of members and friends of the association. All communications should be made to Dr. G. E. Shuttleworth, honorary secretary, or Mr. J. F. Powell, acting honorary secretary, at 8, Lancaster-place, Hampstead.

Royal Mineral Water Hospital, Bath.—The annual meeting of the subscribers to this hospital was held recently. The medical report was satisfactory, and the financial statement showed a deficit remained at the end of 1914 of £427. It is proposed to improve the accommodation of the institution and to provide radiant and other baths at an estimated cost of about £3000. Sir William Osler was elected a governor of the hospital.

Convalescent Home for Children, Weston-super-Mare.—The twenty-first annual meeting of the subscribers to this home at Weston-super-Mare, in connexion with the Bristol Children's Hospital, was held on May 5th. The medical report stated that during the year 285 boys and girls had been admitted; of these, 204 were cured, 60 much improved, 12 improved, and 4 had not improved, and 3 were transferred to the statutory hospital. The financial statement showed the expenditure exceeded the income by £89, and this sum had been met by the Bristol Children's Hospital.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Government and the Drink Problem.

The Government have decided to abandon their proposals to impose additional taxation on beer, wine, and spirits. What they are now asking Parliament to do is to enact the compulsory bonding of whisky and most other spirits for a period of three years. For one year, in order to permit the trade to adapt itself to the new conditions, the withdrawal of spirits ranging from two to three years of age is to be permitted, but a surtax of 1*s.* a gallon will be enforced in this case. Rum and gin, which usually pass into consumption without detention for the purposes of being matured, are still to be allowed to escape compulsory bonding, but they are to be subject to an additional tax in order that they may not be placed at an advantage in regard to other spirits. The Government are proceeding with their Bill to invest them with special powers to control the licensed trade in munition areas.

Army Medical Service.

Some objection was taken in the House of Commons to the proposal in the Army Act (Amendment) Bill which allows a general officer commanding to transfer men from one branch of the military medical service, including the Army Medical Service, to another branch. An amendment was moved with the object of preventing the transfer of men from the Army Medical Service to a combatant unit. The argument was that it was unfair to utilise men who had enlisted on the understanding that they were not to be employed as combatants for the purpose of actual fighting. It was explained that the provision applied only to men, not to officers. Mr. Tennant, the Under Secretary for War, said that where there were sufficient men and circumstances demanded their transfer it ought to be in the hands of the general officer commanding to make the transfer. He intimated that the Director-General of the Medical Service concurred in this view. The amendment was negatived without a division.

Milk and Dairies (Consolidation) Bill.

Mr. Herbert Lewis, the Parliamentary Secretary to the Local Government Board, has presented a Bill in the House of Commons "to consolidate certain enactments relating to milk and dairies." It has been read a first time.

HOUSE OF COMMONS.

WEDNESDAY, MAY 5TH.

Anti-inoculation Literature.

Mr. RONALD MCNEILL asked the Under Secretary for War whether he was prepared to take proceedings under the Defence of the Realm Act against persons attempting, by the distribution of literature or otherwise, to incite soldiers to endanger their own and their comrades' lives by refusing to undergo antityphoid inoculation.—Mr. TENNANT replied: The very satisfactory results which have been obtained by the combined efforts of officers of all ranks, both medical and regimental, as regards inoculation render it unnecessary to consider the question of taking proceedings under the Defence of the Realm Act.

Consultant Surgeons for the Navy.

Commander BELLAIRS asked the Secretary to the Treasury whether the amounts of £5000 a year paid to the six consultant surgeons now specially employed by the Admiralty came before the Treasury before the war broke out, the arrangement to employ them having been sanctioned in 1908. —Mr. ACLAND said in reply: No, sir, the salary was not submitted to the Treasury until the appointments were made. The Treasury gave general approval for the engagement of distinguished surgeons to look after sailors and other naval ratings who might be in need of their help. The scheme for doing this was proposed to the Treasury and sanctioned in principle in 1908, but the amounts intended to be paid were not at that time fixed.

Commander BELLAIRS: In view of the fact that no similar arrangement was made by the War Office, and the fact that the navy has not one-hundredth part of the casualties or the problems arising from casualties which the army has to face, will the Treasury take the fact into consideration and terminate this arrangement?—Mr. ACLAND: No, sir, the Treasury will not terminate this arrangement. It is surely of the utmost importance that our wounded men should have at their disposal the services of these extremely distinguished persons, and I cannot see my way to terminate this arrangement.

Commander BELLAIRS: Will the honourable Member take into consideration the fact that very distinguished surgeons and medical men are now serving in the army upon the pay of an ordinary colonel, and does he not see how undesirable it is that these comparisons should be drawn?—The DEPUTY SPEAKER: Order, order. That is a matter for debate.

Commander BELLAIRS asked the Secretary to the Admiralty whether, in view of the fact that there were so few casualties in the navy which had not been dealt with by the regular surgeons of the navy, he would consent to transfer the services of these six consultant surgeons to the War Office.—Mr. MACNAMARA answered: That is covered by a reply which has already been given.

Commander BELLAIRS: Is the right honourable gentleman aware that there are two gentlemen at the Admiralty, Fellows of the Royal College of Surgeons, who are doing nothing but clerical work? Will he consent to give a return of the number of operations performed by these gentlemen and the number performed by surgeons at the regular hospitals?

The DEPUTY SPEAKER: That is rather a subject for debate.

Commander BELLAIRS: I will put a question down.

Nitric Acid Fumes.

Mr. ROWLANDS asked the Home Secretary whether his attention had been called to the inquest held at Dartford on April 29th into the death of a workman while employed in some gun-cotton works, from the effects of nitric acid fumes; whether he had had a report of the case; and whether the precautions taken were such as to prevent a recurrence.—Mr. MCKENNA replied: I have received a report from the medical inspector of factories who investigated the case and attended the inquest. It appears that the workman had full opportunity of escaping from the fumes, but was unaware of their dangerous nature. The inspector has recommended the issue of instructions to the workmen and certain other precautions which should prevent a recurrence of any similar accident, and the firm has undertaken to adopt the necessary precautions. The matter will be carefully watched.

THURSDAY, MAY 6TH.

Civilian Medical Men and the War Office.

Mr. JOYNSON-HICKS asked the Under Secretary for War whether any civilian doctors were employed by the army at salaries of upwards of £3000 per annum; if so, who were they and what were they paid; and how many civilian doctors were receiving rates of pay higher than doctors of corresponding rank in the Royal Army Medical Corps.—Mr. TENNANT answered: There are no civilian medical men receiving higher rates of pay than officers of corresponding rank in the Royal Army Medical Corps and the Army Medical Service.

Commander BELLAIRS: Will not inconvenience arise from the fact that the Admiralty are paying four times as much as the Army?

The DEPUTY SPEAKER: I would remind the honourable member that this is not the time for argument.

Bangour Asylum.

Mr. HOGGE asked the Under Secretary for War whether Bangour Asylum was being converted into a military hospital, and, if so, what arrangements were being made so that the treatment of the present inmates was not interfered with.—Mr. TENNANT answered: Yes, sir, Bangour Asylum is being converted into a military hospital. I should be glad if my honourable friend would address the second part of the question to the Secretary for Scotland.

Exhaustion and Nerve Shock in the Army.

Colonel WHITE asked the Under Secretary for War whether arrangements had now been made whereby men, and more especially non-commissioned officers, who had been serving in the firing line for many months, and who were suffering from exhaustion and nerve shock, might be granted furloughs of six weeks to two months in cases where the reserve units of their regiments could supply the deficiency so caused.—Mr. TENNANT said in reply: All non-commissioned officers and men who in the opinion of the medical authorities are suffering from exhaustion and nervous shock and require rest are sent home until they are recovered.

Artificial Limbs for Wounded Soldiers.

Replying to Mr. PARTINGTON, Mr. TENNANT said: Arrangements have been in existence for many years whereby a soldier who has, while serving, lost a limb in consequence of disease or injury, is provided with an artificial limb at the public expense. The Commissioners of the Royal Hospital, Chelsea, arrange for the supply of artificial limbs to such soldiers.

Asphyxiating Gases.

Colonel WHITE asked the Under Secretary for War whether protective helmets or masks against asphyxiating gas had actually been issued to the troops at the front.—Mr. TENNANT replied: When the Germans first introduced gas as a weapon of warfare we sent out 1,000,000 respirators, which were supplied to us originally from the Admiralty. These respirators were not found to be so efficacious as we desired, and they were supplemented by another form of respirator, the cotton waste, which was saturated with a solution of carbonate of soda and hyposulphite of soda, being held in place by a veil. That is now being used by the troops. The question has arisen whether it would not be preferable to have a helmet such as is used by fishermen, which is made of woollen material with talc spaces for the eyes, the cotton waste inside being saturated with the same solution. Dr. Haldane has again gone to the front to conduct experiments with these various materials and methods.

The Duty on Medicinal Alcohol.

Mr. HORNER asked the Chancellor of the Exchequer whether, having regard to the fact that ethyl-alcohol, upon which duty was payable, was essential in the manufacture of many medicines used in both human and veterinary practice, the Government would allow a rebate to be granted to the manufacturers or other means adopted by which this duty would not become a tax upon the alcohol used in their preparation, seeing that otherwise the imposition of the contemplated duties would largely increase the cost of these medicines to all users, and thus press with excessive severity upon the poor and add enormously to the expenses of hospitals and charitable institutions.—Mr. LLOYD GEORGE answered: The whole question is under consideration.

International Opium Conference.

Sir J. D. REES asked the Secretary of State for Foreign Affairs whether any and, if so, what action was to be taken upon the correspondence respecting the Third International Opium Conference; whether it was proposed to pursue this matter further during the continuance of the war; and, if not, with what object the report of the British delegates was to be presented to Parliament as soon as the *protocol de clôture* was officially received from the Netherlands Government.—Sir EDWARD GREY replied: No further action has been taken beyond depositing the ratification of the signature of the British delegates, nor is it practicable to take any further action at present. The correspondence respecting the third conference, including the report of the British delegates and the *protocol de clôture*, was laid before the House in February last in accordance with an undertaking given in the House with the object of making all the available information accessible to those members and the general public who are interested in this question.

TUESDAY, MAY 11TH.

Release of Medical Personnel.

Lord ROBERT CECIL asked the Secretary of State for Foreign Affairs what progress had been made for the release of medical personnel detained in the various belligerent countries.—Sir Edward Grey replied: As will be seen from White Paper No. 8 (Miscellaneous) His Majesty's Government accepted in its main outline the interpretation placed by the German Government on the provisions of the Geneva Convention dealing with the release of medical personnel, with the reservation that such personnel should not be detained in connexion with new work. The German Government pointed out that there were certain epidemics amongst the prisoners in German detention camps which require expert assistance. This referred principally to typhus, which had broken out amongst Russian prisoners, and in which disease Russian doctors were more expert than German doctors. On further consideration, His Majesty's Government decided that circumstances, such as the outbreak of obscure epidemics among prisoners, might arise in which the captors might be justified by humane considerations in retaining medical personnel who are thoroughly competent to deal with the disease for a period longer than that which is ordinarily permissible. A note to this effect was addressed to the United States Ambassador on April 30th, and an answer has not yet been received.

Medical Consultants to the Navy.

Commander Bellairs asked the Secretary to the Admiralty whether the highest medical rank in the Navy was that of surgeon-general at a full-pay rate of £1300 per annum, and, if so, whether this fact was taken into full consideration when the arrangement was made to remunerate consultants for short duty at the rate of £5000 per annum.—Mr. Macnamara replied: A surgeon-general of the Navy when employed at any of our naval hospitals draws a salary of £1300 and charge pay at the rate of £182 10*s.* per annum. He is also in the occupation of a house valued at £70 per annum. All the facts bearing on the question were taken into consideration when deciding on the remuneration to be paid to consultants.

Mr. James Hope asked the Secretary to the Admiralty whether the number of civilian doctors now in the service of the Navy was in excess of the needs of that service; and whether he would sanction the transfer of a limited number of such doctors to the service of the army.—Mr. Macnamara replied: The answer to the first part of the question is in the negative. In these circumstances it would not be possible to adopt the suggestion contained in the second part. As regards the special consultants to whom reference has been made in an earlier question, if a specific request were made for help of one of them for any particular operation or for any special consultation, it would be certainly acceded to if it was possible; but the daily duty that has to be performed by these gentlemen in naval hospitals would not allow of the utilisation of their services by the army to a greater extent than this.

The Drug Fund.

Mr. Snowden asked the Chancellor of the Duchy of Lancaster whether he had received a resolution passed by the Insurance Committee for the borough of Blackburn appreciating the action proposed to be taken by the Insurance Commissioners respecting the deficits in the drug funds of the various overspent Insurance Committees for the year 1913, and expressing the desire that a Departmental Committee be appointed to inquire into the causes of and remedies for the continuing deficiencies in the Drug Fund in insurance areas, and for an amendment of Article 40 of the Medical Benefit Regulations; and whether it was intended to carry out these suggestions.—Mr. Montagu replied: The answer to the first part of the question is in the affirmative. In reply to the last part, the cost of the supply of drugs under the Insurance Act is already the subject of inquiry by a Departmental Committee which has been specially appointed for the purpose. Before considering any further action I am awaiting their report.

Salaries of Cork Panel Practitioners.

Mr. Crean asked the Chancellor of the Duchy of Lancaster whether he was aware that the salaries of the panel doctors of the city of Cork are now six months in arrear; whether the Insurance Commissioners in dealing with the county panel doctors paid only three months' salary about three months ago, six months' salary being then due; and whether he would have this state of things attended to immediately in the interest of the service.—Mr. Montagu said in reply: I am informed by the Irish Insurance Commissioners that further payments on account will be made to the doctors referred to both in the county borough and the county in a few days.

WEDNESDAY, MAY 12TH.

Consulting Surgeons with the Army.

Commander Bellairs asked the Financial Secretary to the War Office, in view of the fact that the Admiralty were paying six consultant physicians and surgeons serving on shore in Great Britain at a rate equal to 3·9 times the pay of the highest-salaried surgeon-generals of the navy, in addition to the earnings of a certain amount of private practice, whether any difficulties had thereby resulted in regard to the distinguished civil surgeons who so patriotically went to France at the ordinary rates of army pay.—Mr. H. Baker answered: No, sir. There have been no difficulties with regard to the pay and status of the consulting physicians and surgeons working with the army in France.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Anderson, A. W., M.D., C.M. Edin., has been appointed Medical Officer of the Stewartry Parish of Kirkgunzeon.

Barlow, Sir Thomas, M.D. Lond., F.R.S., has been elected to serve on the Senate of the University of London.

Bligh, J. A. Murray, M.D. Liverp., has been appointed Honorary Physician to the David Lewis Northern Hospital.

Dawson, J. Maxwell, M.D., C.M. Edin., D.P.H., has been appointed Medical Officer of Health for the Burgh of Buckhaven, and Medical Superintendent of the Cameron Hospital.

Harper, John Maurice, M.R.C.S., has been appointed temporary Medical Officer of Health for the Bath Rural District.

Judd, Charles F., M.B., B.Ch. Dubl., has been appointed Medical Officer for the Stillorgan Dispensary District.

Mitchell, T. C., M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer of Health for the Wath Rural District.

Parsons, Leonard G., M.D. Lond., M.R.C.P., has been appointed Lecturer in Infant Hygiene and the Diseases Peculiar to Children in the University of Birmingham.

Wells, S. R., M.D. Lond., has been elected to serve on the Senate of the University of London.

Williamson, James, M.B., Ch.B., has been appointed an Honorary Ophthalmic Surgeon to the Bury Infirmary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

Alton, Hants, Lord Mayor Treloar Cripples' Hospital.—Two Assistant Resident Medical Officers. Salary as arranged, with board, residence, and laundry.

Birkenhead Borough Hospital.—Female Senior and Junior House Surgeons. Salary £180 and £150 per annum respectively, with board and laundry.

Birmingham General Dispensary.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, attendance, &c.

Birmingham, Jaffray Branch of General Hospital, Gravelly Hill.—Resident Medical and Surgical Officer. Salary £150 per annum, with board, residence, and washing.

Birmingham and Midland Eye Hospital.—Senior House Surgeon Salary £110 per annum, with board, residence, and attendance.

Birmingham and Midland Hospital for Skin and Urinary Diseases.—Clinical Assistant for three months. Salary at rate of 52 guineas per annum. Also Clinical Assistant, for six months, to Electrical Department. Salary at rate of 52 guineas per annum.

Birmingham, Romsley Hill Sanatorium for Consumptives.—Assistant Resident Medical Officer, unmarried. Salary £250 per annum, with board, apartments, and laundry.

Bolingbroke Hospital, Wandsworth Common, S.W.—Resident Medical Officer. Salary £300 per annum. Also House Surgeon. Salary £100 per annum, with board-residence.

Bolton Infirmary and Dispensary.—Third House Surgeon. Salary £170 per annum, with apartments, board, and attendance.

Bournemouth, Royal Victoria and West Hants Hospital (Boscombe Branch).—House Surgeon for six months. Salary £100 per annum, with board, lodging, washing, &c.

Brighton Education Committee.—Temporary Junior School Doctor. Salary at rate of £350 per annum.

Bristol, Beaufort War Hospital.—Chief Resident Physician.

Bristol General Hospital.—Second House Physician, House Surgeon, Casualty House Surgeon, and Resident Obstetric Officer, all for six months. Salary at rate of £150 per annum, with board, residence, &c.

Bristol Royal Infirmary.—Throat, Nose, and Ear House Surgeon for six months. Salary at rate of £120 per annum, with board, apartments, and laundry.

Burnley Union Workhouse.—Resident Assistant Medical Officer or Locum Tenens. Salary £200 per annum, with apartments, rations, washing, and attendance.

Burnley, Victoria Hospital.—House Surgeon. Salary £135 per annum, with residence, board, and washing.

Bury Infirmary.—Senior and Junior House Surgeons. Salary £175 and £150 per annum respectively, with board, residence, and washing.

Buxton, Derbyshire, Devonshire Hospital.—Assistant House Physician for six months. Salary £100 per annum, with apartments, board, and laundry.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £200 per annum, with apartments (not board).

Carmarthen, Joint Counties Asylum.—Temporary Second Assistant Medical Officer. Salary at rate of £200 per annum, with board, lodging, washing, &c.

Croydon Borough Hospital.—Senior Resident Medical Officer and Bacteriologist. Salary £200 per annum, with board, residence, and washing. Also Assistant Resident Medical Officer. Salary £150 per annum, with board, residence, and laundry.

DENBIGH, NORTH WALES COUNTIES ASYLUM.—Second Assistant Medical Officer. Salary £220 per annum, with apartments, board, attendance, and washing.

BIRTHS.

BROADBENT.—On May 7th, at Muswell-rise, Muswell-hill, N., to Dr. and Mrs. Reginald Broadbent. a daughter.

BROMLEY.—On May 7th, at The Warden's House, Guy's Hospital, the wife of Lancelot Bromley, M.C., F.R.C.S., of a daughter.

GASKELL.—On May 10th, at the Royal Naval College, Greenwich, the wife of Fleet-Surgeon Arthur Gaskell, R.N., of a son.

MACGLASHAN.—On May 4th, at Hartley-hill, Leeds, the wife of Dr. Keith B. MacGlashan, of a daughter.

SEYMOUR.—On May 7th, at Rosslyn-hill, Hampstead, the wife of Dr. E. A. Seymour, of a son.

SMITH.—On May 2nd, at the Taunton Nursing Home, Taunton, the wife of Lieutenant C. E. H. Smith, R.A.M.C., of a son.

SOWRY.—On May 6th, at Newcastle, Staffs, the wife of George H. Sowry, M.D., F.R.C.S., of a son.

TURNER.—On May 8th, at Anerley-road, Upper Norwood, the wife of Captain A. Scott Turner, R.A.M.C., of a daughter.

MARRIAGES.

BREMNER—LILLICO.—On May 8th, at the Parish Church, Croydon, Lieutenant-Colonel James Morrison Gardiner Bremner, M.B., to Kathleen, second daughter of Alderman William Lillico, J.P., Coombe Hill House, Croydon.

LUKYN-WILLIAMS—MACDONALD.—On May 5th, at Guilden Morden Parish Church, Herbert Temple Lukyn-Williams, M.B., Lieutenant, R.A.M.C., to Matilda Kate, daughter of the late Rev. C. J. MacDonald, B.A.

MAWSON—O'FARRELL.—On April 28th, at the Catholic Church, Haddington-road, Dublin, Dr. Owen Mawson, to Ellen, eldest daughter of Surgeon-General O'Farrell.

DEATHS.

BAILLIE.—On May 3rd, at The Larches, Tiverton, Peter Baillie, M.D. Edin., formerly of Whitworth, Lancashire.

JEFFERSON.—On May 4th, at West-street, Rochdale, Arthur John Jefferson, M.D. Lond., aged 59 years.

LOCKER.—On May 7th, at Kirby Cross, Essex, Edward Hawke Locker, M.R.C.S., L.R.C.P., late Surgeon R.A.M.C., aged 57 years.

MASON.—On May 7th, at Waxham Cottage, Gorleston, Alfred Leighton Mason, L.D.S. Eng., aged 34 years.

STIVENS.—On May 9th, at Park-street, Grosvenor-square, W., Bertram Herbert Lyne Stivens, M.D., of Garlogs, Stockbridge, Hants, in his 60th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

WINKLES.

IN the appeal of Leavett *v.* Clark heard by the Divisional Court recently, the appellant had been convicted under the Larceny Act, 1861, of which Section 24 imposes a penalty upon a person taking "fish" in any water which is private property or in which there is a private right of fishery. In this instance the defendant was picking up winkles upon certain mud flats, gathering some which had been left dry by the tide and others which were still in the water. The magistrates had decided that a winkle was a fish, and the Divisional Court was asked to hold that it was not and declined to do so. The difficulty arose out of the Act in question giving no definition of the word "fish," as to which the legislature seems to have been equally silent on other occasions. Counsel contended that a "fish" must be vertebrate and that the Act was designed to protect the ownership of something capable of being taken by angling. The principal case referred to was that of Caygill *v.* Thwaite, decided 30 years ago by a court consisting of Mr. Justice Mathew and Mr. Justice A. L. Smith, both of whom, it will be remembered, sat later in their lives in the Court of Appeal. In Caygill *v.* Thwaite the point was whether a "crayfish" was a fish. The name, of course, indicates nothing, as crayfish is a corruption of "écrevisse," and Mr. Justice Mathew, as Lord Reading pointed out in his judgment in Leavett *v.* Clark, could only say, "It is, perhaps, difficult to give any definite reason except that crayfish are fish." The Lord Chief Justice, Mr. Justice Avory, and Mr. Justice Low appear to have found scarcely better grounds for their decision, which was to follow Caygill *v.* Thwaite, as it had been so long held to be good law. The last-named judge is reported to have observed that he "saw no reason why a winkle should not be a fish." It may be suggested that some day definition should prevent the possibility of a man, who might honestly not know that he was doing wrong, being convicted as a fish poacher by establishing the true position of the "fractious penny winkle" and other molluscs.

WORK OF SCHOOLS FOR MOTHERS IN EDINBURGH.

IN the provincial Training College at Edinburgh a lecture was delivered recently under the auspices of the Edinburgh Child Study Association, entitled "Schools for Mothers as Centres for Social and Educational Work," by Miss E. V. Eckhard, Manchester. The lecturer said new enterprises were usually initiated by private effort, and when the value of an enterprise had been fully proved the State stepped in and offered help. Schools for mothers had now passed the experimental stage, and the State was giving financial help in England. The aim was to educate the mother through the child.

Since Jan. 1st five infant health centres have been opened in various parts of Edinburgh. Nine baby consultations a week are held, with a doctor in attendance. In addition, the centres are opened five other afternoons for health classes for mothers and instruction in infant clothing and feeding.

THE INHALATION OF CHLOROFORM IN BRONCHIAL CATARRH.

To the Editor of THE LANCET.

SIR,—I read with much pleasure Dr. Alfred S. Gubb's letter in your issue of April 24th on the value of chloroform inhalation in cases of violent paroxysmal cough and in the cough in cases of phthisis. In the "sixties" Dr. Churchill, of this city, recommended whiffs of chloroform to cut short paroxysmal cough in pertussis and phthisis, and for the past 30 years I have prescribed it in such cases. I recommend five or ten drops to be inhaled from a piece of fine cotton-wool. I may add that I have also prescribed it in cases of paroxysmal cough in the early stages of measles, and in no single instance have I seen any unpleasant results.

Dr. Richard Pearson, physician to the General Hospital, near Birmingham, writing in 1795 ("Miscellaneous Observations on Certain Remedies Used in Consumption," R. Baldwin, No. 47, Paternoster-row, London), says that he has "found the *vapour of æther* remarkably serviceable in phthisical cases. Patients who have inhaled it two or three times find it so grateful to their feelings that they are disposed to have recourse to it too often." His mode of applying was as follows: "One or two tea-spoonfuls of æther to be poured into a tea-saucer, which is held up to the mouth, and the vapour arising from it is drawn in with the breath. The inhalation is continued till the saucer becomes dry."

We learn from "La Grande Chirurgie de Guy de Chauliac," of 1363, that Theodoric used the vapour of hot water impregnated with an extract prepared from hypnotics and analgesics, such as mandragora, hemlock, and opium, which was inhaled until sleep was induced. Theodoric or Teodorico was an Italian surgeon and ecclesiastic who rose to be Bishop of Cervia. He enjoyed a high reputation for his skill in surgery, and wrote, in Latin, a treatise "On Surgery according to the System of Hugo de Lucca." He died in 1298. I am, Sir, yours faithfully,

Dublin, April 26th, 1915. GEORGE FOY.

THE HOSPITAL ACCOMMODATION OF ENGLAND AND WALES.

Mr. Herbert Lewis, M.P., stated at Hemel Hempstead on May 6th that according to a Census by the Local Government Board the hospital accommodation of England and Wales is as follows:—

	Hospitals.	Beds.
General...	593	31,313
Special	222	13,654
Fever	755	31,149
Small-pox	362	7,946
Port Sanitary	30	418
Poor-law	700	94,001
Total	2662	178,481

COLONIAL VEGETABLE DRUGS.

THE current issue of the quarterly *Bulletin of the Imperial Institute* (Vol. XIII., No. 1) contains an interesting article, covering nearly 40 pages, on Investigations of Vegetable Drugs and Poisonous Plants made by the staff of the scientific and technical department of the Institute and by other investigators during recent years. The drugs examined include many which have a reputation among natives, and all the drugs have their source in the British possessions. Most of the "native drugs" are disappointing from the point of view of European medicine, but there are some notable exceptions, Podophyllum emodi, an Indian plant recognised in the British Pharmacopœia, being one of them. Other examples are the Egyptian plant Hyoscyamus muticus, a valuable source of the alkaloid atropine, the seeds of Peganum Harmala, which have long been used as an anthelmintic in the East, and the seeds of Croton Elliottianus, which Professor J. T. Cash, of Aberdeen University, and Mr. W. J. Dilling have found to be a useful laxative. A special article by Mr. W. R. Dunlop, of the Imperial Department of Agriculture for the West Indies, deals with the lime and lemon as sources of citric acid and essential oils. The *Bulletin* can be obtained from Mr. John Murray, Albemarle-street, W., price 2*s.* 6*d.* net.

"KHAKI": A TOPICAL MAGAZINE.

THE May number of *Khaki*, a magazine written for our sailors and soldiers, which is supplied gratis to them while on active service, contains, in addition to fiction, several articles of topical interest. Among the latter is the story of Turkey's influence in the East, with remarks on the probable site of the Garden of Eden. The magazine is published at Imperial House, Kingsway, London, W.C., at the price of 6*d.* net, and it deserves support, not only on account of its contents but also for the good work which the management of the journal is doing in helping British prisoners in Germany who have no relatives or friends.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Papers:—Mr. H. Moore: On the Corpuscular Radiation liberated in Vapours by Homogeneous X Radiation (communicated by Prof. O. W. Richardson).—Mr. H. Richardson: The Absorption in Lead of γ Rays emitted by Radium B and Radium C (communicated by Sir E. Rutherford).—Mr. T. R. Merton: On the Application of Interference Methods to the Study of the Origin of Certain Spectrum Lines (communicated by Prof. A. Fowler).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

GENERAL MEETING OF FELLOWS: at 5 P.M. Ballot for the Election of Candidates to the Fellowship.

SECTION OF PSYCHIATRY (Hon. Secretaries—Bernard Hart, G. F. Barham): at 6 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

WEDNESDAY.

SECTION OF THE HISTORY OF MEDICINE (Hon. Secretaries—Raymond Crawfurd, Leonard G. Guthrie): at 5 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

Papers:

Dr. George C. Peachey: William Bromfield, Surgeon.
Dr. Charles Mercier: Paracelsus and Van Helmont.
Dr. Hector A. Colwell: Lionel Lockyer.

Exhibits:

Mr. Macleod Yearsley: Two Documents concerning Touching for the King's Evil.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—S. E. Dore, A. M. H. Gray): at 5 P.M.

Exhibition of Cases (at 4.30 P.M.):

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

Dr. J. J. Pringle: Pemphigus Vegetans (shown before).
Dr. J. M. H. MacLeod: (1) Dermatitis Herpetiformis; (2) Chronic Pemphigus (?).
Dr. H. W. Barber: Lichen Planus Atrophicus in an Infant.
Dr. Parkes Weber: (1) Spurious Erythromelalgia: Non-syphilitic; (2) Arteritis Obliterans in a Jew.
Dr. D. Walsh: Pompholyx.
Dr. H. C. Semon: Mycetoma Pedis.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY.—8 P.M., Cantor Lecture:—Dr. D. Sommerville: Foodstuffs. (Lecture IV.)

ILLUMINATING ENGINEERING SOCIETY, House of the Royal Society of Arts, 18, John-street, Adelphi, W.C.

TUESDAY.—8.15 P.M., Discussion on Some Points in Connexion with the Lighting of Rifle Ranges.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE, 11, Chandos-street, Cavendish-square, W.

FRIDAY.—8.30 P.M., Papers:—An Epidemic of African Tick Fever among the Troops in British Somaliland.—American Leishmaniasis.—Treatment of Bilharziasis by Thymo-Benzol.—Treatment of Ankylostomiasis by Milk of Higueron.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M. Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	1	0	One Year	£1	5	0
Six Months	0	12	6	Six Months	0	14	0
Three Months	0	6	6	Three Months	0	7	0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

The Hunterian Lecture

ON

SOME INFECTIONS OF THE TONSILS.

Delivered before the Royal College of Surgeons of England on Feb. 19th, 1915,

BY FREDERICK C. PYBUS, M.B., M.S. DURH., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND; SURGEON TO THE HOSPITAL FOR SICK CHILDREN, AND SURGICAL REGISTRAR TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

(*Concluded from p. 1012.*)

STREPTOCOCCUS INFECTIONS.

THIS constant inhabitant of the mouth, fauces, and tonsils may live in apparent harmony with the individual during the whole course of his life. At times it causes serious lesions, and is perhaps the most important pathogenic organism in the tonsil. There is no doubt that several varieties are present; these differ in their morphology and cultural reactions and in their virulence and effect on inoculation. They are one of the commonest sources of acute infection, causing catarrhal inflammation, lacunar tonsillitis, tonsillar and peritonsillar inflammation, and suppuration. They not infrequently cause cervical bubo and suppuration, while they may cause septicæmia or endocarditis after their entry into the blood.

In addition to these acute manifestations, which are accompanied by fever and general illness, their effects may be more subtle. After an acute attack or even without it the tonsils may become permanently infected and be subject to recurring attacks of mild inflammation on the least provocation, not only during childhood or adolescence, but even well into adult life. It is probable that hypertrophy in childhood is due in part to the presence of these organisms. After infection, although no active signs be present in the tonsil, a continuous mild infection may be proceeding, as shown by a slight enlargement of the tonsillar lymph glands, general ill-health, and that type of anæmia due to the hæmolytic properties of the streptococcus poison. The tonsils may show all stages from mild inflammation to suppuration; they may hypertrophy or become in the final stages a shrunken fibrous body, containing débris in the lacunæ and being adherent to the pharyngeal wall. These manifestations of streptococcus tonsillitis are well recognised.

Rheumatism.

Perhaps one of the most important streptococcic infections is that modified variety which is associated with the production of rheumatism, and it is to this form that I shall devote most time.

The association of tonsillitis and rheumatism has been so well known and long established that the term rheumatic sore-throat has passed into general acceptance. Tonsillitis so often preceded an attack of acute rheumatism that the tonsil was suspected of being the possible entrance of some organism. It is chiefly owing to the work of Poynton and Paine that the various manifestations of this disease have been collected together into a homogeneous whole, and they have shown that this infection may manifest itself in almost any tissue or organ of the body. The investigations of Poynton and Paine on the organism they consider the cause of rheumatism, and the later and additional work of Beattie, Dixon, Walker, and others have shown that the organism found in acute rheumatism, although appearing in the lesion as a diplococcus, on cultural examination grows in chains and belongs to the streptococcus group. The evidence that this organism is the chief causative agent in the production of acute rheumatism is accumulating, and its acceptance amongst the profession is increasing.

The evidence that the tonsil is one of the chief sources of the organism is as follows. Rheumatic fever is often preceded by an attack of tonsillitis, and recurrence of the lesions may be preceded also by tonsillitis. The presence of the streptococcus of the rheumatic type in the tonsil has been experimentally proved. The tonsil can be found affected in most cases of rheumatism, and lesions can be found there in persons dying of endocarditis, acute or chronic. The original case of Poynton and Paine was that of a patient with chronic endocarditis. Following an attack of tonsillitis organisms were isolated from the tonsil showing the usual characters of their organism. On inoculation into a rabbit endocarditis was produced. These experiments have been so often performed by Poynton and Paine, all Koch's postulates being fulfilled, that the chain of evidence of this organism being the one concerned in the production of rheumatism seems complete.

A series of experiments of Beattie and Yates are important in this connexion. (Table VII.) Material from various lesions in the joints, throat, and blood was examined in 192 cases, rheumatic and otherwise, for streptococci. The organism was obtained in 48. Of these cases, 7 presented a definite disease and have no relation to the present question. Of the remaining 41 cases there was a rheumatic history in 31. The organism from these in 19 cases, or 61 per cent., on inoculation produced typical lesions in rabbits, these lesions being characterised by acute non-suppurative synovitis. Of the 11 negative results in rheumatic cases, 8 were from the tonsils. In each of these cases a single colony was subcultured, and there being many varieties of streptococcus present in the tonsil it may be presumed that a non-virulent form was obtained. If 2 additional cases, presumably rheumatic, are included, the positive results reach 70 per cent. in these cases, while in the non-rheumatic cases typical arthritis was not produced

TABLE VII.—*Inoculation Results (Beattie and Yates).*

Rheumatic Cases.

Number of experiments.	Source.	Arthritis.	Septicæmia.	No effect.
8	Synovial membrane	5	0	3
15	Throats	7	0	8
3	Blood	3	0	0
1	Cerebro-spinal fluid	1	0	0
1	Pyorrhœa alveolaris	1	0	0
3	Heart valve (vegetations) ...	2	1	0
	Non-rheumatic Cases.			
6	Synovial membrane	1	5	0
1	Blood...	0	1	0
1	Appendix...	1	0	0
1	Subcutaneous abscess... ...	0	1	0
	Doubtful Cases (Tonsillitis without History).			
5	Tonsils	1	4	0

in a single instance. In the experiments with organisms obtained from the tonsils of those with a rheumatic history, 15 in number, a positive joint result was obtained in 7, or 47 per cent. Of inoculation from the tonsils where no history of rheumatism was obtained, 5 in number, septicæmia was produced in 4 animals and arthritis in 1, the latter being possibly of the rheumatic type.

Chorea.

It is interesting to note that a positive result was also obtained from the organism found in the cerebro-spinal fluid in a case of chorea. It has been shown that the organisms from the tonsils of rheumatic patients are capable of reproducing in animals acute synovitis and endocarditis. The same organism has been found in other lesions of rheumatism, especially chorea. The diplococcus rheumaticus has been isolated from 3 fatal cases of the condition by Poynton and Gordon Holmes, where it was found in the pia mater and endocardium. The histological characters of the brain lesion in these cases, together with the cultural findings, support the title given by these authors to this condition—namely, cerebral rheumatism.

Chorea of pregnancy is in the majority of cases probably identical with that of children. French and Hicks in an analysis of 29 cases found that 19 had a previous history of rheumatism, while 15 out of these 19 had suffered previously from chorea. In 3 fatal cases, which were associated with fever, endocarditis was found post mortem. Wall and Andrews in an analysis of 37 cases found a previous history of chorea in 23 cases; if to these be added other rheumatic manifestations 28 out of the 37 had suffered previously. They also quote Buist's figures, in which out of 266 cases of chorea during pregnancy 66 had previously suffered from chorea during childhood. In one case which I had the opportunity of examining the patient's attack of chorea during pregnancy followed an attack of tonsillitis, and I found the tonsils enlarged with evidence of absorption—enlargement of the tonsillar glands.

The relation of hypertrophied tonsils to Sydenham's chorea has been investigated clinically by Branson, who found that of a series of 75 children 21 per cent. had been operated on for enlarged tonsils and glands. Naso-pharyngeal lesions were present in 88 per cent. of these children with chorea, and 62 per cent. had enlarged tonsils or had been operated on for them. Showing the evidence of infection from their tonsils all these cases had enlargement of the corresponding lymphatic glands. In 1910 I advocated the removal of tonsils for chorea where infection was considered to be occurring from them. This measure has been attended with considerable success, and has shown that the tonsil is one of the chief sources of infection, but that others exist in the naso-pharyngeal region, one case being unaffected by the operation until a chronic suppurating ear was cured. The removal of the tonsil cannot be relied on with certainty to cure the condition at once, but presumably cuts off further infection, for as in other rheumatic lesions, particularly endocarditis, the organism may remain latent in the affected tissues for varying periods.

Chronic Arthritis and other Lesions.

There is also accumulating evidence that certain forms of chronic arthritis have a definite relationship to infection from the fore end of the alimentary canal, in which the tonsil takes a share. Poynton and Paine have produced changes in the joints in rabbits by their diplococcus undistinguishable from rheumatoid arthritis in man. Beattie and Yates have also produced chronic arthritis by means of an organism obtained from a case of tonsillitis. Reinoculation from this joint produced similar changes in a second series of animals. They have shown that relapses are due to the reactivity of organisms lying latent in the synovial membrane, which they have proved that they are able to do for periods varying from a week to a year. Whatever other causes may be found for rheumatoid arthritis there is no doubt a certain number are due to infection from oral sepsis, and infected tonsils form an important part of this lesion.

In addition to the above-mentioned situations to which these organisms may be carried by the blood stream—namely, the heart, pericardium, meninges, or joints—occasionally they may pass into the appendicular artery and infect the appendix vermiformis. In spite of the large amount of operative work carried out in the treatment of appendicitis the mode of infection is still obscure, although the frequency of a streptococcal infection has been abundantly demonstrated. In the majority of cases the organisms invade the lining membrane directly, but in other cases the infection arrives by the blood stream. Appendicitis has been produced experimentally for some time by inoculating the blood with various organisms. Acute tonsillitis and appendicitis may occur at the same time. Kelly mentions that in 91 cases of acute appendicitis at the Johns Hopkins Hospital 3 were preceded by acute tonsillitis by a few hours. Finney and Hamburger also mention 3 cases of associated appendicitis, tonsillitis, and rheumatism. Poynton and Paine mention a case of associated tonsillitis and appendicitis. From both lesions they cultivated a streptococcus with identical appearances. That from the throat on inoculation produced arthritis, while that from the appendix when inoculated into 6 rabbits produced 1 case of appendicitis. In another series of experiments with the diplococcus obtained from a rheumatic joint, out of 8 animals inoculated arthritis was produced in all, while appendicitis was produced in 2. In the complete series of 16 intravenous inoculations 3 cases of appendicitis were produced. This would seem to bear out the noted occasional relationship of rheumatism to appendicitis.

Amongst other rheumatic lesions may be mentioned acute neuritis, which I have observed following an attack of tonsillitis. After successive attacks, the nerve of Bell, the anterior tibial nerve, the descending branches of the third and fourth cervical nerves, and the musculo-cutaneous nerve of the arm were affected. In the three former limited paralysis followed, which recovered in the course of a year. One of the attacks occurred after incomplete removal of the tonsils. Since the septic stumps were removed three years ago there have been no further attacks.

The Tonsil as Site of Entry for Organisms.

The foregoing evidence points to the tonsil being one, if not the chief, site of entry for the rheumatic organism. Other factors undoubtedly are concerned. There is no characteristic size, shape, or appearance of the tonsils—any variety may be present. All cases, however, give evidence of disease. The tonsils are infected and the tonsillar glands enlarged. The signs may be those of acute tonsillitis, or the process may be a chronic one with an entire absence of fever or signs of active mischief in the tonsil itself.

With regard to treatment, prevention of tonsil infection is undoubtedly the most important. When the organ, however, is grossly diseased and causing glandular or systemic infection, and where its recovery has been shown impossible, it should be enucleated as a preventive against further infection. This removal should be carried out during some quiescent period both of any local inflammation or general infection.

PNEUMOCOCCUS.

It has been mentioned that the pneumococcus can frequently be found in the tonsils of apparently healthy persons. On occasion an invasion may occur leading to tonsillitis. The inflammation may be limited to the tonsils, or the pharynx may be involved in addition. The inflammation may be associated with the presence of a fibrinous exudate on the surface, while in other cases a deeper infection of the tonsil may result, leading to a tonsillar abscess. In some cases the lesion may be associated with a similar infection in the lungs. One case of note has come under my observation—a child with a large abscess situated in the region of the tonsillar gland. On evacuation of this abscess a pure culture of the pneumococcus was obtained. At the same time the tonsil on the affected side was found to be enlarged and a culture of the pneumococcus obtained from it. On the removal of the tonsil at a later date a small abscess was found in its substance from which a similar culture was obtained.

OTHER PYOGENIC ORGANISMS.

The remaining pyogenic organisms are capable of infecting the tonsil and causing lesions in it or in more distant parts. All the types of tonsillitis are produced, with infection and perhaps suppuration of the cervical lymph nodes. Systemic invasion occasionally occurs with the staphylococci and streptococci and leads to a blood infection of either septicæmic or pyæmic type. In these cases organisms may settle in one or more distant organ, and there is hardly a tissue or organ in the body in which an infective lesion has not been reported following an attack of tonsillitis. In some cases of acute osteitis the source of organisms may be traced to the tonsils, although the great preponderance of staphylococcal infections in these cases points to a dermic origin of the organisms, and this is found clinically to be the case.

Theisen reports a case of acute thyroiditis as following tonsillitis. Loeb reports 4 cases of nephritis from the same source, and although the evidence is not quite conclusive discussion on his cases resulted in 4 more examples being cited. Infections have also been recorded in the testicle, endocardium, lungs, and in the abdominal organs.

Purpura of varying degrees has been not uncommonly noted to follow tonsillitis. I have observed several such cases, one of which presented abdominal symptoms, associated in all probability with hæmorrhagic lesions in the intestine. Somewhat similar effects are produced in the throat by infection with the organisms of Vincent, the bacillus and spirillum. Here the effects may be limited to the tonsil or involve in addition the adjacent pharyngeal structures, lymphatic glands, or distant organs.

SPECIFIC FEVERS.

Time does not permit me more than to mention the relation of the tonsil to the specific fevers. It is well known that the diphtheria bacillus may be a harmless inhabitant of the tonsil, either the true or pseudo type. Its invasion may be limited to the tonsil, and here it produces the characteristic lesion. Once lodged in the recesses of the lacunæ it is often most difficult to get rid of, and may cause repeated attacks of the disease. I removed the tonsils from a patient three years ago, following three attacks of diphtheria within as many years. Diphtheria bacilli were found deep in the lacunæ, and so far no further attack has occurred. These patients carry about an infection not only a danger to themselves but to others, and the most effective way of curing the carrier, when the bacilli are shown to lodge in the tonsils, is to enucleate them. This is followed by a disappearance of organisms from the throat.

The bacillus of influenza has been repeatedly demonstrated in the tonsils both in the apparently healthy and in those suffering from the effects of influenza. It has also been shown that the infection of poliomyelitis may gain access through the tonsils. Tonsillitis may also be associated with the other specific fevers, especially measles and German measles.

The relation to scarlet fever is one of great importance. The attack is so often ushered in by tonsillitis that some causal relation between the two must be considered established. It is still a disputed point how far the streptococci found in the throat lesion and in the infective complications, such as middle-ear disease, cervical bubo, and arthritis or endocarditis, are responsible for the disease.

HYPERTROPHY OF THE TONSILS.

This brief review would be incomplete without some detailed reference to the subject of hypertrophied tonsils. The importance of the subject can be judged from the estimate of the Chief Medical Officer of the Board of Education, who states that of the six million children attending the Government schools 6–8 per cent. suffer from this condition to such a degree as to necessitate surgical treatment. This percentage of children with enlarged tonsils varies in different parts; usually it is higher than the figures above quoted. In London of 240,764 children examined 10 per cent. had hypertrophied tonsils.

It is important to define, if possible, at the outset the normal tonsil, and I would suggest that this is one which causes no symptoms or signs either mechanical or infective. The tonsil naturally enlarges after the age of 2 years and gradually declines in size after puberty. It is found that pathological hypertrophy, although it may occur in infancy, usually corresponds with the period of decay of the milk teeth, and again some time after the development of the secondary ones.

Mouth-breathing and Caries.

The effects of enlarged tonsils may be mechanical, causing difficulty in speech or deglutition. More important, however, are the results of infection, either in the tonsil itself or in the lymphatic glands or body generally. I have previously mentioned some of the more important varieties and results of infection. Apart from those rarer cases of enlargement of the lymphoid tissues generally—such as occurs in lymphatic leukæmia, in which the tonsil participates—the main factor in causing hypertrophy is infection, the infection resulting from the presence of organisms in the mouth and throat.

The enlargement of the pharyngeal tonsil, with the consequent establishment of mouth-breathing, is a factor in the production of tonsillar hypertrophy. One way in which it acts is to transfer to the mouth and throat the duty of filtering the inspired air. The second is in the production of dental caries, which is aggravated by mouth-breathing. This relationship is illustrated in Table VIII., taken from Dr. Wheatley's report. In children of 5 years with adenoids of such degree as to lead to mouth-breathing carious teeth were present in 16·7 per cent. in excess of the others. In children of 12 years of age with a similar condition the excess of carious teeth was 22·7 per cent. A third factor, if the results of Lenart's experiments are confirmed, is that the tonsil may receive organisms by means of its afferent lymphatics from the nose.

TABLE VIII.—*Adenoids causing Mouth-breathing.* (*Dr. Wheatley's Report, 1911.*)

Children aged 5 years—	
Caries in excess of others ...	16·7 per cent.
Children aged 12 years—	
Caries in excess of others ...	22·7 per cent.

The relationship of carious teeth to tonsil hypertrophy is shown by the greatest frequency of hypertrophy in the fifth, sixth, seventh, and fourteenth years of life. At this earlier time the greatest number of carious teeth are usually present, while at the later period the first molars may also become carious. The high percentage of enlarged tonsils in those with carious teeth is well shown in the table from Dr. Jones's report. (Table IX.)

TABLE IX.—*Showing Percentage of Enlarged Tonsils and Number of Carious Teeth.* (*Dr. Jones's Report, 1911.*)

Carious teeth	0	1-4	over 5
Enlarged tonsils	41·9%	52·8%	67·0%

This relationship can be demonstrated clinically by the beneficial effect on tonsillar hypertrophy by rendering the mouth clean. The reports of the Chief Medical Officer of the Board of Education abound in tables, statistics, and important information relative to these facts.

The specific fevers play an important part in the production of tonsillar enlargement, and one is struck by the frequency by which all trouble is dated from an attack of scarlet fever, diphtheria, or measles.

Condition of Tonsils and Glands.

The degree of hypertrophy of the tonsil varies greatly, some being so large as to meet in the middle line. This type is one which lies almost entirely beyond the faucial pillars and is pedunculated. In other cases, however, the tonsil may reach an extreme grade of enlargement without projecting beyond the anterior pillar of the fauces. The shape of the tonsil also varies greatly. Several distinct types may be recognised, but there are numerous intermediate forms. From being a hollow organ the hypertrophied tonsil tends to become more and more solid owing to the accumulation of lymphoid tissue around the lacunæ, until eventually these become narrow channels, having their orifices obstructed and tending still more to produce the stasis of their contents, and the accumulation of organisms and débris within them. This renders the lacunæ more susceptible of infection by damaging their delicate epithelial lining, and also accounts for the formation of the plugs in the lacunæ or in the main tonsillar fossa. After infection has persisted for some time the tonsil tends to become more fibrous and to diminish in size. In spite of this diminution in size the tonsil still remains septic and may continue to manifest its condition accordingly. It is important to realise that the enlargement of the tonsil may be temporary and capable of completely subsiding. This is well exemplified by the re-examination of school children two or three months after inspection, when the tonsil enlargement may have completely subsided and no evidence of infection can be obtained.

In order to determine the condition of the tonsil as far as possible, in addition to mere inspection of the throat the patient should be made to retch, when the tonsils are forced forwards and towards the middle line and stand out prominently. Under these conditions their exact size and shape can be determined. In order to judge of their septicity, if this is not manifest on simple inspection, the tonsillar fossa or lacunæ should be explored with a bent probe. In all cases the tonsillar glands should be examined by palpation while standing behind the patient, and in a large percentage will be found to be enlarged. Dr. Priestley in his 1910 report gives the following table (No. X.) in which the relation of enlarged tonsils to enlargement of the cervical glands is shown.

TABLE X.—*Relation of Enlarged Tonsils to Enlarged Cervical Glands.* (*Dr. Priestley's Report, 1910.*)

Children.	Number examined.	Enlarged tonsils.	Enlarged cervical glands.
Years—5- 6	8487	19·5 per cent.	23·4 per cent.
,, 6- 9	8578	19·6 ,,	18 7 ,,
,, 12-14	4749	20·5 ,,	10·7 ,,

Analysis of a Recent Series of 100 Cases.

Amongst the commonest symptoms repeated sore throats, tonsillitis, peritonsillar suppuration, and enlargement of the tonsillar glands are the most important. Evidence of more general infection may be manifest, such as anæmia or endocarditis. It is important to notice that attacks of acute tonsillitis in these cases may be conspicuous by their absence, the whole process being insidious and gradual. An analysis of a recent series of 100 cases operated on by me gives the following results. (Table XI.)

TABLE XI.—*A Series of 100 Cases.*

Sore throats	70 (70%)	Removal—		
Tonsils—		Complete	190	(95%)
Large	34 (34%)	Incomplete	8	(4%)
Medium	42 (42%)	Shape—		
Small	24 (24%)	Common	123	(61·5%)
Glands—		Embedded	70	(35%)
Large	14 (14%)	Projecting	6	(3%)
Medium	20 (20%)	Glands tuberculous ...	11	(11%)
Small	62 (62%)	Recurrent	4	(4%)
Infection	120 (60%)			

70 per cent. of the patients had suffered from attacks of tonsillitis or sore-throat. The tonsils were considerably enlarged in 34 per cent. of the cases and moderately enlarged in 42 per cent. The remainder were judged to be of normal size or atrophic. In 96 per cent. the tonsillar lymphatic glands were enlarged, being definitely palpable in 82 per cent. In 14 per cent. the glands were sufficiently large to demand surgical treatment, and in 11 per cent. of the cases were considered tuberculous. In 20 per cent. the glands were moderately enlarged, being easily palpable and in most cases visible.

Gross infection—shown by the presence of débris, pus, or foreign bodies—was found in 60 per cent. of the tonsils removed. Four cases had previously been operated on, and needed a second operation for tonsillitis or enlarged glands. For the removal of the 198 tonsils the guillotine was used in every instance. 95 per cent. of these tonsils were completely removed in their capsule, in one piece in the majority of cases; occasionally, however, owing to the size or shape of the tonsil it was necessary to remove it in two or more pieces. The tonsils were definitely pedunculated in only 3 per cent. of the cases; the embedded type was present in 35 per cent.; while the common variety, that with the projecting and almost solid lower pole, with the upper part hidden between the pillars and forming a cavity surrounded by folds of lymphoid tissue, was present in the remaining 61 per cent.

TREATMENT.

The principles to be adopted in the treatment of tonsillar disease may be summed up as follows. So far as the individual is concerned, where the symptoms are mainly or entirely mechanical, and fail to subside in three months after removal of any source of infection, partial removal may suffice. Tonsillotomy, however, has this disadvantage—the basal portion of the tonsil may enlarge and again cause symptoms. In addition to this many hypertrophied tonsils, so far as can be ascertained on inspection, do not appear to be grossly infected. In those cases which are grossly infected the basal portion, often the most diseased, is left behind and may commence to give trouble, especially if some of the lacunæ become partially or entirely sealed up in the process of healing.

When infective symptoms predominate in the tonsil itself, such as acute tonsillitis or chronic lacunæ infection, or when the tonsils are in addition enlarged, any source of infection must be removed, especially carious teeth. Nasal breathing must be re-established, and the case watched to see the effect of the treatment. Where the tonsil is too severely affected to be capable of recovery, as judged by the recurrence of symptoms and the failure of the above measures, then total removal is indicated. Enucleation of the tonsil must necessarily prevent tonsillitis, and while it does not entirely prevent pharyngitis such attacks are usually materially lessened in frequency. When repeated quinsies have occurred further attacks may be prevented by removing the source of the infection, the tonsil.

For lymphatic gland infections, where tuberculosis is suspected tonsillectomy is indicated; the course of the glandular enlargement determines whether this also may require operation. In pyogenic infections of the glands the tonsil must be dealt with when the acute lymphadenitis has subsided or been operated on if suppuration has supervened. Chronic glandular enlargement of the mild or moderate degree is so frequently met with in hypertrophied tonsils that when the tonsil recovers its normal character the glands subside also. It should be a rule that no tonsil should be removed when acutely inflamed. For more distant infections, when the tonsil is suspected of being the focus, removal is indicated when the general condition is satisfactory.

In all these cases total removal is the operation of choice. It presents no greater danger than incomplete removal and can be readily accomplished by the guillotine alone, by a method first described by Mr. Whillis and myself in January, 1910. While these methods directed to the individual are of great importance there is no doubt that prevention of tonsil infection should be our chief aim. This is to be obtained by the advance of hygiene, personal, in the home and school. The maintenance of nasal respiration, the prevention of dental caries, and the proper supply of food in sufficient quality and quantity will greatly diminish the prevalence of this condition. The provision of a cleaner air supply and the prevention of infection by milk are measures needing attention. When that delicate balance between health and infection is upset and the tonsil, a useful organ, becomes diseased and incapable of recovery, a timely removal of this focus may prevent more grave illness and disability. The question of infection of the tonsil and from the tonsil is not to be summed up in some form of operative procedure, but by the attention to the numerous measures I have tried to indicate.

BRITISH MEDICAL ASSOCIATION.—The annual Representative Meeting will take place at the Connaught-rooms, Great Queen-street, W.C., on July 23rd.

THE TREATMENT OF STAMMERING.—A clinic for the treatment of stammering is being conducted at St. Thomas's Hospital for children who are already under treatment at the hospital for some other disease. The patients are treated twice a week in instructional classes.

A NOTE ON THE TREATMENT OF SEPTIC WOUNDS.

BY A. MARMADUKE SHEILD, M.B. CANTAB., F.R.C.S. ENG.,
CONSULTING SURGEON TO ST. GEORGE'S HOSPITAL.

HAVING undertaken the care of a number of surgical beds in one of the Exeter emergency hospitals, I wish to offer a few remarks on the treatment of septic wounds. The excellent articles which have lately appeared in THE LANCET from Sir Watson Cheyne, Sir Almroth Wright, and others have been most valuable and helpful to the whole profession.

It is obvious from the general trend of modern experience that removal of all foreign substances, free drainage, and especially the mechanical washing away of discharges from every pocket and recess, are of more importance than the use of antiseptic fluids, which can have little or no effect on organisms in the diluted state in which lotions can be safely employed. Warm saline fluid is probably as good a "flushing agent" as can be used. I have seen no great stress laid on the use of long immersions in a warm water bath. For wounds of the limbs this is an invaluable method. I used constantly to employ it for septic wounds about the anus and perineum, especially in bad fistula cases. The results were striking, and doubtless due to mechanical removal of pus and organisms, the fluid percolating and penetrating everywhere.

I was particularly impressed with the wisdom of Sir A. E. Wright's remarks on the treatment of sepsis by physiological methods. This has been too little considered. Everything that improves the health, strength, and appetite promotes healing and diminishes sepsis. It was this long ago which led Paget to give that ancient but excellent drug—the yellow bark—to his patients, and to advise the air of Margate and the East Coast for patients suffering from tuberculous wounds and glands. And this brings me to speak of a consideration which, I fear, has not received the attention its importance deserves. I refer to the marvellous influence of constant exposure to air and sun on those suffering from discharging and septic wounds. Having experienced the benefit of this in my own long and desperate illness, I am able to speak with some confidence. The rapid healing of wounds in animals and savages, with no treatment, has long been known. A gunshot fracture of the limb of a pheasant or hare will unite readily, under a covering of earth, feathers, and fur. I have been informed that the Zulus carried their wounded to the top of a high hill and there left them, recovery being rapid and sound. Nothing is more striking than the rapid recovery from even bad wounds, among country or sea-faring folk, as compared with the pallid occupant of a London slum. In my past practice I frequently sent down to the east coast cases of wounds which were tedious in healing, and the promptness of recovery was generally quite noteworthy. I feel sure that in hot summer weather buildings in a large city are not ideal places to promote the bodily vigour essential to combat the discharges and exhaustion of a septic wound.

It is unfortunate to have to criticise arrangements already made, but, speaking with all respect, I cannot but regard the crowding of wounded into large cities as faulty. I believe at Cambridge a large "open-air" hospital is established with good results. It would be very interesting to hear the views of the surgeons there on the value of such an institution, especially on the health of the nurses and attendants. I believe the air of high altitudes and of the east coast to be the most beneficial.

I fear that many of these remarks are empirical, and I leave to the bacteriologists the explanation of an undoubted and important clinical fact. It is unfortunately only too likely that in the coming months our arrangements will be inadequate. I strongly urge upon the authorities the establishment of matchwood hut hospitals, or tents, on high commons, or on the coast, rather than crowd the wounded into improvised hospitals in towns. It would be less costly. Cases of an offensive nature are easily isolated. The making of latrines would do away with risks of bad drainage. There is no risk of fire, and this is not one to be ignored in case of a Zeppelin raid. The health of nurses and attendants is maintained at a high standard. There would be no need to send away patients to convalescent homes.

I should be glad if this article would promote discussion on an eminently important matter, and the opinion of leading surgeons is earnestly to be desired.

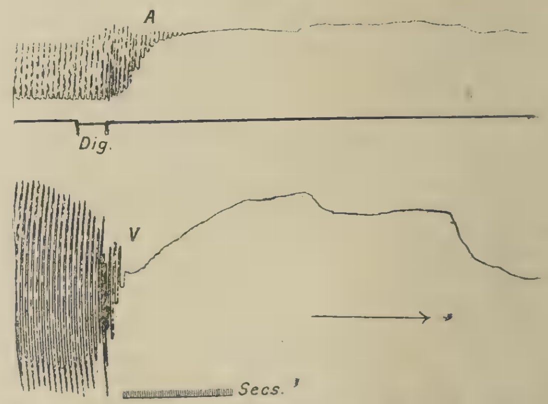
Budleigh Salterton.

HEART PERFUSION WITH EXCRETORY TOXINS.

BY D. T. BARRY, F.R.C.S. ENG., M.D. R.U.I.,
PROFESSOR OF PHYSIOLOGY, UNIVERSITY COLLEGE, CORK.

BY way of comparison with the action of excretory toxins on the heart, a record (Fig. 1) is here given of that of digitalin which bears a certain resemblance to them. A 1 per cent. solution of digitalin in Ringer's fluid quickly caused arrest of both auricle (upper tracing) and ventricle (lower tracing) in this toad's heart. The heart rapidly dies with digitalin of this strength, so that neither perfusion with Ringer's fluid nor other means can restore activity in the muscle. With weaker solutions recovery may be brought about. Digitalin has a uniform toxic action on the whole heart muscle. Schmiedeberg[1] considered the effects of digitalin to be a loss of elasticity in the muscle.

FIG. 1.



Records of tracings of (A) auricle and (V) ventricle of toad's heart after treatment with digitalin, 1 per cent., in Ringer's fluid.

The heart is exposed to the action of certain excretory toxins of the urine and fæces when the mechanism of their expulsion is defective, or, it may be, to these toxins or their precursors normally on their way to elimination. It was thought advisable to test this action by perfusion of the toad's heart.

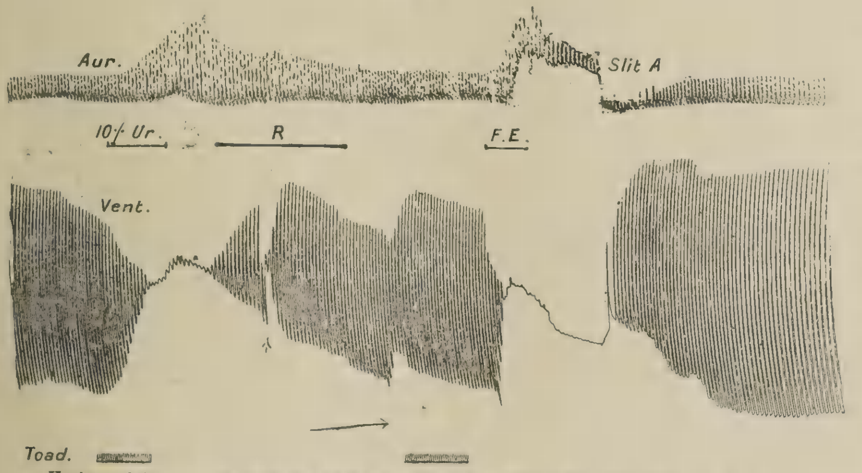
---

[1] Schmiedeberg: Beiträge zur Anatomie und Physiologie, Leipzig, 1874, p. 222.

Method.—The inferior vena cava below the liver was isolated and a small cannula inserted. This procedure as described by Mines[2] is made easier by allowing a drip from the cannula which clears the slit in the vein wall. A cannula communicating with three perfusion bottles has been used in the present instance; one contained freshly prepared Ringer's solution, the second a mixture of human urine and Ringer's solution, and the third fæcal extract made with Ringer's solution. Strengths of 10 and 15 per cent. have been tried. Up to the latter concentration the extracts are practically neutral to litmus; the hydrogen ion concentration was not determined. The aortæ are cut across to provide a free exit to the fluid. A uniform velocity of feed is arranged by adjusting stopcocks on the supply tubes.

The toxicity of these solutions is greatly diminished by boiling and by allowing them to stand for a few days. If 10 c.c. of urine are evaporated to dryness and extracted with 10 c.c. of water and 90 c.c. of Ringer's fluid the solution has very little toxic effect, which practically disappears if the residue be incinerated before extraction.

FIG. 2.

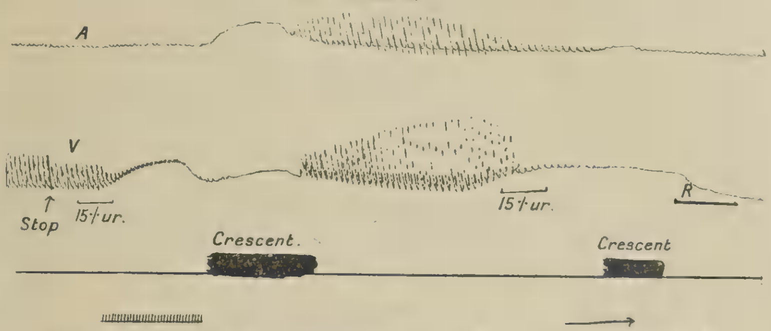


Horizontal lines marked UR, R, and F.E. represent perfusion with urine, Ringer's fluid, and fæcal extract respectively; time in seconds.

The first toxic effect is exhibited by the ventricle. A 10 per cent. urine solution in a few seconds brings about cessation of this chamber in a state of tonus (Fig. 2); the small "beats" seen on the ventricular record are due to auricular pull. The auricular beat is increased in force, which is due, in part at any rate, to increased tension; there was no previous perfusion. Recovery with Ringer's solution is rapid, though the ventricle is somewhat irregular for a time. The break in the recovering ventricle tracing, as shown by the arrow, is due to clipping the supply tube for an instant, thus shutting off the perfusing fluid. The ventricle in its tonic condition took a little time to recover after the passing over of auricular impulses into it. These impulses, powerful though they were, evidently were blocked in their passage to the ventricle until Ringer's solution restored the conductivity of the a.-v. bundle.

Fæcal extract shows a similar result (perfusion period shown by the line marked F.E.). The output from the ventricle being merely passive, the intra-auricular tension is greatly increased, till by making a slit in its wall the tension is relieved; the lever falls to the previous diastolic level and the ventricle beat is at once resumed with the now quietly acting auricle. It is pretty evident here that the depression (block) was mainly confined to the a.-v. bundle, the ventricle proper, although in a state of tonus, being ready to take up the beat vigorously the moment it was passed on by the extra stimulus provided by the snip.

FIG. 3.



Lines marked UR and R represent periods of percussion with urine and Ringer's fluid respectively.

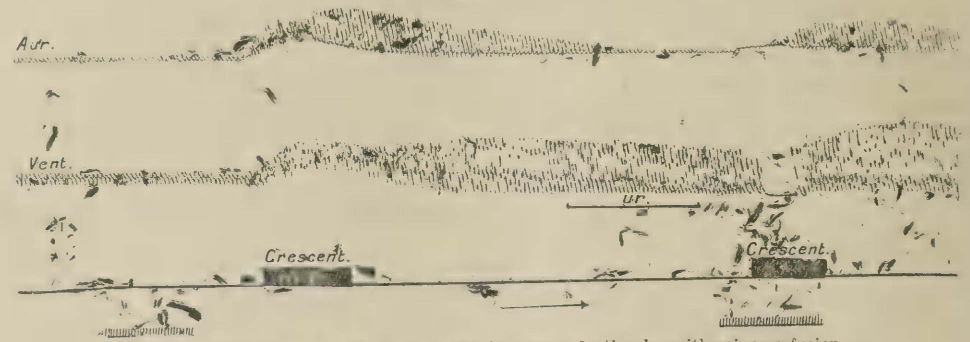
A second application of the fæcal extract in this case had a slight effect on the auricle, while the ventricle beat was diminished, but diastole was not interfered with (no tonus). Apart from the fact that the conditions were considerably altered in this by the leak on the auricle — the perfusion pressure was not altered to meet it—there seems to be a certain degree of tolerance of, or immunity from, the toxins on their repeated use. This is exhibited by a slower onset of the effects and a diminution of the tonicity. If we turn on the urine solution we notice an improvement in the auricular beat, an improvement which cannot be ascribed simply to tension changes, bearing in mind the leak and the fact that the fæcal extract solution at the same velocity previously caused no augmentation of beat; the ventricle gradually grows weaker. It will be, of course, evident that the ventricle is not brought under the influence of the fluid to the same extent as before the auricle was slit. A certain amount of antagonism seems to exist between these poisons, but the question has not been properly investigated.

---

[2] Mines: Journal of Physiology, xlvi., p. 188, 1913.

The a.-v. bundle seems to be the part most affected by the excretory toxins which depress its conductivity, at the same time that they affect somewhat the ventricular muscle as a whole; a marked difference in the mechanisms of the two chambers is also demonstrated by their action. Irritability of ventricular muscle is completely lost only with strong solutions, and is quickly recovered if the action be not too long continued. The nervous mechanism, except the accelerator fibres, seems to be unaffected by the weaker solutions.

FIG. 4.



First crescent, stimulus with Ringer perfusion; second, stimulus with urine perfusion.

In the tracing (Fig. 3) the drum was stopped for a little while to try to get a more effective pull on the auricle lever, but without success; the attachment of the silk was not interfered with. A strong solution of urine, about 15 per cent., causes marked tonus of the ventricle with a greatly diminished fundamental beat. Stimulation of the crescent (first signal mark) during this tonus causes arrest of both chambers, the auricle entering into a state of well-marked tonus. It will be noticed that there is no initial contraction of the ventricle (muscle irritability lost). At the end of the stimulation period both chambers beat regularly and forcibly. Perfusion with the same solution a second time is followed by a similar result, but crescent stimulation (second signal) is not followed by heart contractions. Perfusion with Ringer's solution (shown by line marked R) for about half a minute brings about recovery of the muscle irritability, as contractions, not shown in figure, occur at the beginning of the next stimulation period. Sympathetic stimulation, not shown in the record, at this period when the muscle shows recovery with Ringer's fluid, is capable of setting up rhythmic contractions at once; if it fails it is because the accelerators, more susceptible than the inhibitors, have also been recently stimulated and have not quite recovered. This third stimulation is followed after a short interval by strong rhythmic contractions in both chambers. A third dose of the poison causes arrest of the ventricle almost in diastole. The tonic effect, as already mentioned, disappearing. The muscle again recovers, as shown by contractions at the beginning of the fourth crescent stimulus, which is followed after an interval by strong regular beats.

The auricle throughout is not affected in the same way as the ventricle; during the third and fourth stimulation periods it is scarcely affected, and it continues to beat while the ventricle is quiescent. The interpretation of the results seems to be that urine in the strengths given has a toxic action on ventricular muscle, while a deleterious effect on the auricle is not apparent. Its depressing action on the a.-v. bundle is distinctly marked, a depression which seems to be in part muscular and in part nervous. The third and fourth stimuli cause a short arrest of the auricle and maintain the arrest of the ventricle. It would seem that inhibitor nerves are not paralysed, and it may be that the stimuli by acting on these help to prevent ventricle recovery; but the muscle and accelerator depression have not sufficiently recovered to respond to stimulation. There is a difference of susceptibility not only in the muscle of the two chambers but also in their nerves, the accelerators to the ventricle suffering more than the auricular ones; any marked interference with these latter soon causes a cessation of the beat.

To show the action of urine on the accelerator nerves a weak current is applied to the crescent of a fresh heart perfused with Ringer's solution. (Fig. 4.) It is followed by well-marked acceleration and augmentation. It is now perfused with a weak solution of urine that is not enough to cause marked deterioration of the beat, and so might obscure results, and the same stimulus applied. It causes a pure inhibition, affecting mainly the ventricle. There is little doubt but that the accelerators have been depressed by a solution which is too weak to cause any marked change in the muscle. The toxic effect of a weak muscle poison is to a great extent counterbalanced by the beneficial mechanical effect of perfusion: the weak urine solution here employed if dropped on a non-perfused heart causes after a little time a distinct weakening of the beat, although it affects mainly superficial muscle and not the susceptible a.-v. bundle. Again, the depression of the accelerators is not sufficient to interfere with the rhythm, the effect of the previous stimulation being probably to a certain extent antagonistic in this respect; but it is enough to bring out as the result of a weak stimulus the other factor (inhibitor) in the nervous balance, at any rate in so far as it affects the ventricle.

Cork.

THE ECONOMY OF THE ARMAGH GUARDIANS.—By 21 votes to 6, the Armagh guardians, on May 11th, refused to pay a substitute for Dr. R. T. Herron, medical officer of Armagh union infirmary and fever hospital, while the former was engaged at the front in His Majesty's forces, giving as a reason that they were bound to consider the ratepayers' money as if it were their own. Dr. Herron was a civil surgeon with His Majesty's forces at the time of the South African war in 1901–02, and was awarded a medal with four clasps.

THE INFLUENCE OF INJECTIONS OF CONTRA-TOXIN NO. 4 (MEHNARTO)

ON THE CONTENT OF OPSONINS IN THE BLOOD SERUM OF TUBERCULOUS PATIENTS.

BY R. TANNER HEWLETT, M.D. LOND.,
F.R.C.P. LOND., D.P.H.,
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON;
DIRECTOR OF THE BACTERIOLOGICAL DEPARTMENT,
KING'S COLLEGE, LONDON;
AND
DR. LOUIS RAJCHMAN.

WE examined the influence of injections of contra-toxin No. 4 on the content of opsonins in the blood serum of patients under treatment. The technique employed was the classical one. Seventy-nine tests were made in all. Bacteria were counted in 100 leucocytes, two films were made from each test, and the indices determined after two examinations. Table I. gives the results obtained with patients under treatment.

TABLE I.—(*Fifteen Patients under Treatment*).

Patients.	Before injection.	After injection one week.	Two weeks.	Three weeks.
1	0·32	—	1·36	0·9
2	0·46	—	—	0·78
3	0·26	0·6	1·08	1·4
4	0 19	0·22		—
5	0·16	0·66	2·2	—
6	0·71	0·82	0·75	1·1
7	1·07	2·04	1·17	—
8	0·91	0·5	1·2	—
9	0·31	0·92	1·3	—
10	0·89	1·81	—	—
11	1·56	1·7	—	—
12	1·8	1·2	1·6	—
13	0·9	1·2	0·9	—
14	1·65	1·5	—	—
15	1·23	1 4	—	—

It was thought necessary to determine the behaviour of the opsonic index in normal persons injected with contra-toxin No. 4 so as to ascertain the influence of contra-toxin on normal blood serum. Table II. gives the results obtained with three "normals"; they were persons free from tuberculosis but suffering from gonorrhœa. It will be observed from the table that no distinct increase in the opsonic index against B. coli and staphylococcus could be recorded.

TABLE II.—"*Normal*" *Controls*, 1.

Patients.		Before injection.	One week after injection.	Two weeks after injection.
"N" ..	B. coli	1·06	0·73	0·82
	Staphylococcus	0·85	1·12	0·96
"P" ..	B. coli	1·6	2·04	1·9
	Staphylococcus	0·96	1·36	0·85
"G" ..	B. coli	0·82	0·75	0·90
	Staphylococcus	1·2	1·1	1·4

It was further thought necessary to carry out another control experiment in order to ascertain the opsonic index against tubercle bacilli in "normal" persons. Two persons suffering from neurasthenia and free from tuberculosis were selected. (Table III.) There was a slight increase in the opsonic index in the case "Edward"; but this increase was insignificant as compared to that recorded with tuberculous patients under treatment.

The above figures show that the opsonic content distinctly increased after injections of contra-toxin No. 4 in almost every case, and that in six of them the increase was very marked. It is difficult to say at the present moment whether the increase of the opsonic index against tubercle bacilli is a permanent one. Cases 1, 7, and 13 seem to indicate that after an initial increase there may be diminution, which, however, remains above the level of the opsonin content before treatment. It is, however, an open question for how long this increase continues, as no patient was examined for a longer period than four consecutive weeks.

TABLE III.—"*Normal*" *Controls*, 2.

Patients.		Before injection.	One week after first injection.	One week after second injection.
"Edward"	T.B.	0·83	0·92	1·02
	B. coli	1·1	0·92	0·95
	Staphylococcus	1·2	1·3	1·4
"William"	T.B.	0·76	0·84	—
	B. coli	0·98	0·96	—
	Staphylococcus	1·08	0·85	—

Further Opsonin Tests by Dr. W. E. COOKE and Dr. W. JOHNSTONE.

Further opsonin tests were carried out at the Ochil Hill Sanatorium, Milnathort, by W. E. Cooke, M.D. Liverp., M.R.C.P. Edin., D.P.H. Lond., late Medical Superintendent, Ochil Hill Sanatorium, and W. Johnstone, M.B., D.P.H. Camb., late Resident Physician. They report as follows:—

"In order to ascertain the permanency of the increase of opsonins against the tubercle bacillus in the blood serum of patients treated with contra-toxin No. 4 we extended our tests over a period of four months. In all we treated 25 patients, and the opsonin content in the blood serum of these patients was examined by us. The accompanying table (IV.) gives our results:—

TABLE IV.—*Results of Opsonin Tests at Ochil Hill Sanatorium* (*Dr. Cooke and Dr. Johnstone*).

Case No.	Date of first injection.	1913 19.11	1913 12.12	1913 18.12	1913 26.12	1914 2.1	1914 20.1	1914 27.1	1914 25.2	1914 3.3	1914 23.3

"The above figures lead us to conclude that injections of contra-toxin No. 4 caused a marked increase of opsonins in the blood serum of every tuberculous patient. It will be observed that there is a slight diminution after the initial increase, but one is forced to admit that even after the diminution the opsonin index remains stationary and permanent above the level of the opsonin content before treatment."

PROGRESS IN THE TREATMENT OF CATARACT IN INDIA.

BY HENRY SMITH, M.D., M.CH.R.U.I., V.H.S.,
LIEUTENANT-COLONEL, I.M.S.; CIVIL SURGEON, AMRITSAR.

THE accompanying table, extracted from the official records, shows the progress in the treatment of cataract in India, except in the minor provinces and native States, statistics of which I have been unable to obtain. It shows the work done in the past by the Indian Medical Service and the work we are now doing. It was in the late "seventies" that cataract extraction in India came into existence. Before that time the treatment of cataract was in the hands of the immemorial indigenous "lens coucher." All the progress we have made has been at his expense. The Punjab is his home. All over the Punjab we come across villages named Rawal Pindi—that is, Rawal's town, Rawal signifying the caste of lens coucher. From the Punjab at the end of the hot weather he migrates all over India; a number of them go to Europe and return at the beginning of the following hot weather.

Statistics of the Cataracts Operated on in the Leading Provinces of the Indian Empire.

* Population at Census, 1911.
Total for the above provinces, 31,598.

The statistical table does not indicate the amount of cataract in India. It indicates the amount which has come under modern treatment. When the figures concerning the Punjab are examined it will be seen that, as in the other provinces, results were becoming stationary up to, roughly, the year 1898. Shortly after that date I began to teach extensively and to advocate intracapsular extraction, so that it has now become practically the operation of election in the Punjab. The progress made in the Punjab since 1900, when compared with that of the other provinces, speaks more in favour of intracapsular extraction than volumes of academic disquisition.

The phenomenal progress since 1900 in the Punjab compared with the other provinces of India is undoubtedly due to the superior results obtained by intracapsular extraction. Nothing can controvert these facts. As far as matters surgical are concerned, those who are familiar with the Punjab know that we are dealing with a highly utilitarian people, a people who go entirely by results. Intracapsular extraction is beginning to extend rapidly to other provinces, and when it is extensively adopted I expect to see progress in these provinces similar to what we have in the Punjab. It is being noticed by all who adopt the operation in other provinces that the cases in their hospital rapidly increase in number at the expense of hospitals who adhere to Daviel's operation, thus showing clearly the patient's opinion regarding the comparative excellence of the two operations. I personally believe that it will not be many years before intracapsular extraction is the operation of election throughout the Indian Empire, and that those who stand out against it will disappear from want of material. The table above shows that we do over 31,000 cataracts a year in the Indian Empire, more than half of these operations being performed in the Punjab, with its 20 millions of people, the population of the Indian Empire being 315 millions. Twenty years hence there will be, I think, more than 60,000 cataracts a year coming under modern treatment in the Indian Empire. The fact that less cataract comes under modern treatment in other provinces than in the Punjab does not indicate that there is necessarily less cataract in those provinces. It does indicate that we have not secured the confidence of the patients in the same degree as we have in the Punjab.

I think, without encroaching on other men's work, I may claim to have established intracapsular extraction of cataract in the Punjab and in many other places in India. I do not claim to have been the first man to extract cataract in the capsule. Intracapsular extraction has been the dream of ophthalmologists since the days of Daviel. It has been tried by a number of men we know, and probably by many others whose names we do not know. Their methods were so imperfect that the risks associated with the procedure made it prohibitive, so that at the present hour they would all have ceased to exist.

I do claim that every detail associated with my name has been worked out by myself independent of even a suggestion from any other man; as, for instance, the method of completely exposing the conjunctival sac for disinfection and for exposing the field for the operation; the method and the importance of controlling the orbicularis muscle; the different methods of dealing with the different types of lens; the fact that an eye should not be subjected to meddlesome dressing any more than any other surgical wound, &c. Any one of the technical details which I have pointed out may in itself look trifling. It is only the experienced operator who comes to recognise their importance, and combined these details constitute a method which, as many of my pupils have shown, is not subject to greater loss of vitreous humour than the operation of Daviel in the same hands.

I have also shown that a cataract may be extracted at any stage of its immaturity as safely as when mature. I have thus established it as an operation which is destined to live and, in my opinion, to take the place eventually of Daviel's operation as distinguished from previous evanescent methods of intracapsular extraction.

I also claim that I have been the first man to teach the mechanical side of surgery as the mechanical side of any other part is taught. The practice universal in Europe and America is to teach the mechanical side of the surgical art by means of lectures and demonstrations. What other mechanical art is taught in this way? The procedure I adopt in teaching is to show the pupil in a considerable number of cases the method of operation, pointing out the importance of every detail. The pupil is then set to perform the operation before me on the living subject in a large number of cases. He is instructed as he proceeds, the mistakes he is making are pointed out and the reasons given, and I come to his relief in case of difficulties. A short course of training of this kind makes a man a more efficient operator than a lifetime of lectures or of looking at demonstrations. One advantage in this method of teaching is that it establishes the confidence of the operator in himself, which no other method does, or else forces him to decide that he had better confine himself to the physician's art. I have had as pupils a large number of the Indian Medical Service, of the Royal Army Medical Corps, and of the different missionary societies, together with Hindus, Mohammedans, Parsis, official and non-official, without respect to colour, caste, or creed. I have had surgeons from Great Britain, Australia, Canada, and especially from the United States. To teach men this way is a very strenuous and tiring task, as will be understood when the welfare of the patient is my responsibility and must be the first consideration.

This teaching I have been doing single-handed and alone, unrecognised by Government, in an institution grossly under-staffed and financially starved. It will be understood how much strain is involved when it is stated that the work I have personally done includes more than 35,000 cataract operations, with a corresponding proportion of other ophthalmic operations. It also includes as much general surgery as that done by any other man living. In addition to all this I have had my official work, the management of a jail during most of the time, the administration of the sanitation, medical charities, and medico-legal work of a district close on a million people. It is needless to say that I could not cover in teaching the whole field of ophthalmology in addition to my other work. It would take a "superman" to do that.

Considering that post-graduate schools in the different branches of medicine are springing up over the Indian Empire, and the amount of material represented by the foregoing statistics, it is surely time that we had a post-graduate school to teach the subject to those pursuing a career in ophthalmology in the Indian Empire. We should not leave post-graduates to the meagre material of our alien enemies, since it is to Vienna and Berlin men go for post-graduate instruction rather than to Great Britain. I would point out that the number of cataract operations in London in the year does not exceed 400–600, and in Vienna there are a few more.

It may be said that this is not the time to raise an issue of this kind, when the Empire is in labour. I contend that this is just the time when "the spirit is on the waters." The spirit is abroad throughout the Empire that we should develop our own industries and not be dependent on other countries, a sentiment with which I wholeheartedly agree. Why should not India take its position in the scientific field of ophthalmology, since it has incomparably more material than any other country in the world? It is a subject which surely appeals to every man in India. All we require to establish a school of ophthalmology in India is money. I hope our patriotic fellow citizens will respond to the crying need of the land of their birth. A school of this kind must be properly manned and financed. Its incumbents should not be paid on the principle that they are to eke out a meagre existence by means of private practice, competing with men who will do a cataract operation for 2 rupees. If it is to be a success, their pay and prospects should be so ample as to attract the best men available, as the prospect of private practice for such men may safely be calculated as approaching *nil* from this time onwards.

The Government is advancing rapidly as regards the improvement and development of their medical schools for undergraduates. Government is also instituting research schools and schools of tropical medicine all over India for post-graduates, but nothing has been done to promote instruction and research in surgery post-graduate. The gulf which stands between European and Indian is being very slowly bridged. Among the builders of this bridge the surgeon stands out pre-eminently. It is he who has paved the way for modern sanitation and modern medicine, though both are yet in their infancy. From the sweeper to the gaddi the surgeon comes most closely in touch with the real life of the people and their aspirations. He is their friend and confessor, so to speak; a man of no political authority and in no way connected with the "taxation of the poor" or the "punishment of the innocent." Surgery makes an infinitely greater appeal to the people of this country than medicine. The indigenous medicine man still flourishes under the shelter of superstition and fate, neither of which can shelter the surgeon's art; hence the fact that surgery is the pioneer and paves the way for medicine. So, I think, of post-graduate schools, one for surgery and surgical research should lead the way.

It is a mistake to think that because there are a large number of Indians becoming qualified in medicine, therefore medicine may safely be left to take care of itself in India. India never required higher-class men than it does at present and will do for many years to come, to lead the newly fledged profession in the way which experience in Europe and America has indicated, with all its humanitarian, scientific, and æsthetic aspirations. The whole tendency of the Indian profession, becoming so rapidly produced, is competition for fees, thus reducing fees to such a low scale that it is impossible for such a profession to devote any attention to the development of the scientific side of its art, the whole tendency being to reduce the profession to a mere trade, in which he who advertises loudest reaps the biggest financial advantage. We are told that Indians do not possess the scientific spirit. I think there is much truth in this statement at the present time. The study of science is but in its infancy in India, and we cannot therefore expect to see its people realising the seductive satisfaction to be gained by scientific research and its application to the alleviation of human suffering. Yet a people who for ages past have produced so many ascetics prepared to work through life for spiritual idealism, despising material welfare, have surely unlimited possibilities for the future of producing men who will give their lives to the interests of science, which are the interests of humanity.

The objects of this school which I advocate are: the study and teaching of the causes and prophylaxis of the many diseases to which the eye is incident in India; the teaching, both theoretically and practically, of the methods of treatment of diseases of the eye; and the utilisation of our material to such a degree that men and women from all the world will come for instruction to India.

TWO EXTRAORDINARY CASES OF LIVER ABSCESS.

By CLAUDE BURGOYNE PASLEY, F.R.C.S. IREL.,
MEDICAL OFFICER, TAIPING, FEDERATED MALAY STATES.

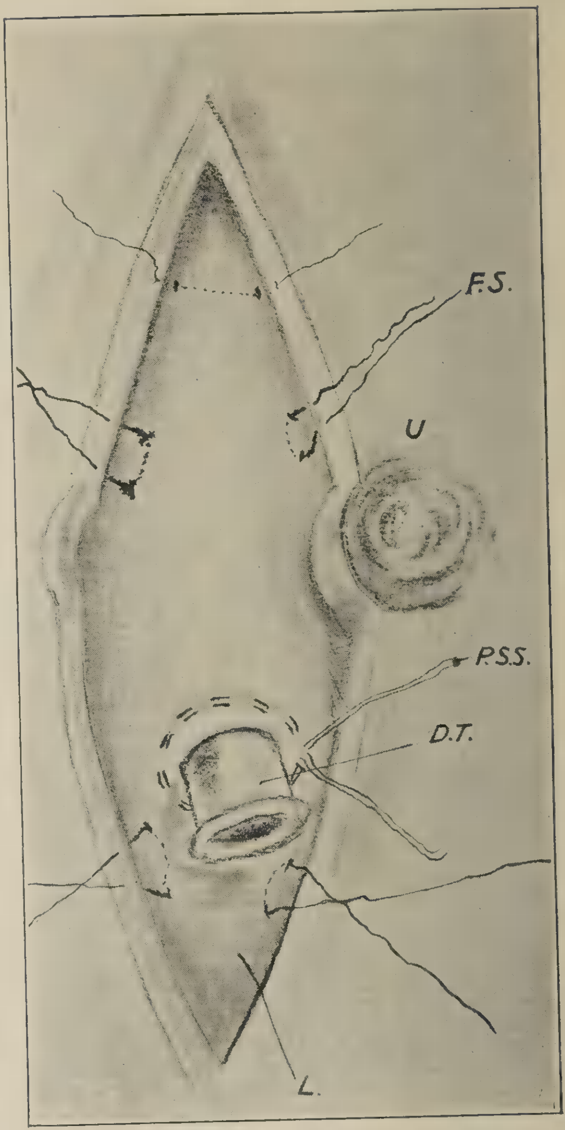
LIVER abscess in the Federated Malay States is fairly common, but the two following cases are, I think, worthy of record from the fact of their remarkable size, larger than I can find recorded in any publication that I have been able to consult, and also for the reason that although the patients were extremely emaciated and constitutionally extremely ill they both recovered perfectly, thus showing that no liver abscess, however large and however ill their possessors may be, can be considered as hopeless.

CASE 1.—The patient, a Chinese mining coolie, aged 40 years, was admitted to hospital on Nov. 9th, 1914. He complained of a large slightly painful swelling in the abdomen, which he first noticed one and a half months previously. There was a history of dysentery three months prior to admission and lasting for about 14 days.

On examination the abdomen was found enormously distended, resembling closely the abdomen at full-term pregnancy. An enormous tumour was palpable, which gave the sensation of fluid under extreme pressure. It was slightly tender to touch. Absolute dulness extended from the pubic region up to and continuous with the hepatic area proper. The tumour extended equally into both umbilical regions laterally—in fact it practically filled the abdominal cavity. The patient's general condition was extremely bad; he was wretchedly thin, weak, and listless. There was absolutely no sign of jaundice, and no bile in the urine. Blood examination showed slight leucocytosis. Examination of stools gave a negative result. A provisional diagnosis of liver abscess was made and operation decided upon.

On Nov. 23rd I opened the abdomen in the middle line, the incision extending from a point 3 inches above to 3 inches below the umbilicus, thus thoroughly exposing the anterior aspect of the tumour. On passing my hand into the abdomen I was able to trace the tumour right down to the pubic symphysis upon which its lower sharp edge rested, and also upon the iliac fossæ on either side, extending laterally as far as the ascending and descending colic regions. Upwards it became continuous with the liver. No adhesions were encountered. The abdominal cavity having been most thoroughly packed off with sterile towels, I passed an exploratory needle into the tumour and evacuated a small quantity of thick yellow pus. A purse-string suture was then inserted around the area where I proposed freely to open the abscess and place a large drain. I next passed several fine silk sutures between the parietal peritoneum and that forming the liver capsule in such a way as to surround the area opened, and thus shut it off from the general abdominal cavity; these sutures were not tightened and tied until the abscess had been evacuated. I next plunged "Manson's" liver abscess trocar and cannula into the abscess at the site of the primary puncture. Pus under enormous pressure gushed out, and the abscess quickly emptied itself. I passed my finger into the abscess cavity subsequent to withdrawal of the cannula, but utterly failed to reach its limits. A large rubber drainage-tube was inserted and the purse-string suture tightened so as to prevent any leakage. The toilet of the surface of the liver having been attended to and the packings being removed, the fixation sutures were tightened and tied, thereby approximating the liver surface to the parietes. (Fig. 1.) A point of suture was passed

FIG. 1.

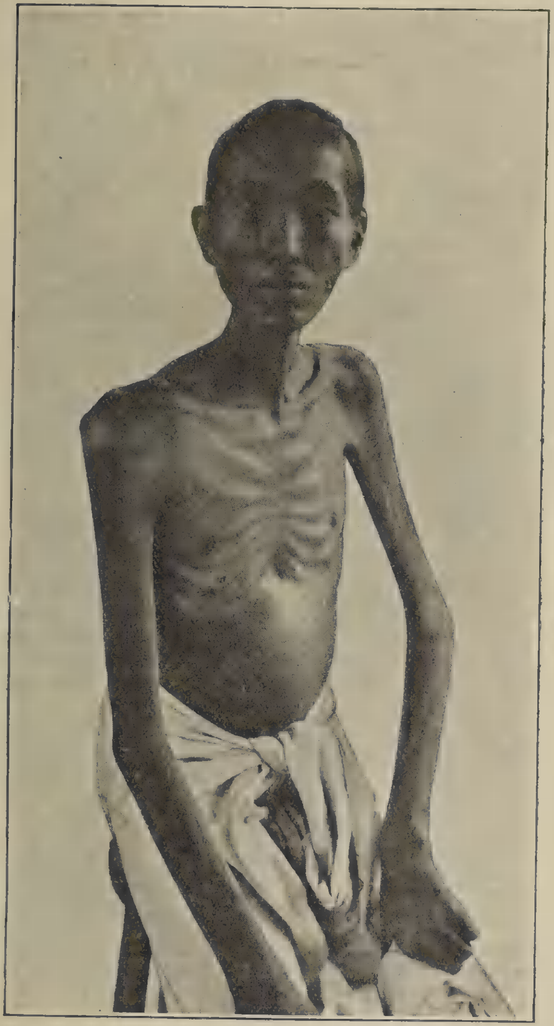


Illustrating method of operation, the parts being nearly life size. F.S., Fixation sutures. U., Umbilicus. P.S.S., Purse-string sutures. D.T., Drainage-tube. L., Liver.

between the abdominal wall and the drainage-tube, and the abdominal wound completely closed save where the tube extruded. I now placed a short glass tube to act as a window between the drainage-tube and a length of rubber tubing, which was allowed to terminate in a chamber containing carbolic lotion, thus encouraging drainage by syphonage.

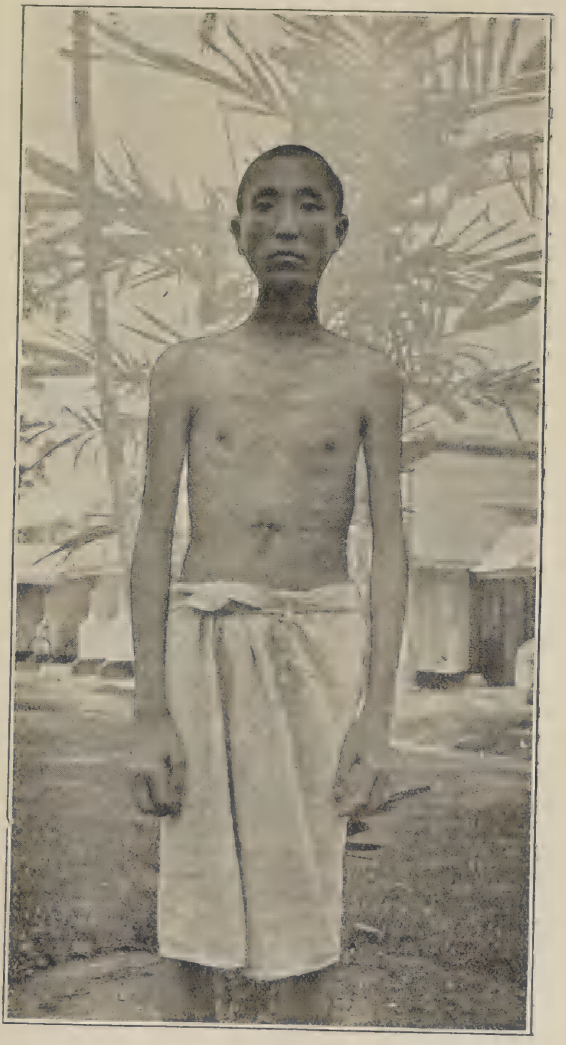
The patient stood the operation well, and his subsequent history was quite uneventful; the drainage-tube was finally removed on the fourteenth day after operation. For a further fortnight the abscess continued to drain through the sinus formed and gradually ceased, when the sinus itself slowly healed from the bottom. The patient rapidly improved, putting on weight, his appetite becoming very keen. His bowels acted regularly, and the motions were in every way normal. No amœbæ were found in swabbings taken from the abscess cavity. The only medicine given during his illness was emetine administered daily by hypodermic injection. He received 1½ grains per day.

FIG. 2.



CASE 2. Before operation.

FIG. 3.



Same patient after operation.

CASE 2.—The patient, a Chinese male aged 33 years, was admitted to hospital on Nov. 22nd, 1914. He complained of gradual increase in the size of the abdomen, and stated that he first noticed the increase during the earlier part of October. He had little or no pain; he complained, however, of progressive loss of strength and weight. He stated that he had an attack of dysentery about three months prior to the onset of his present trouble.

On examination an enormous tumour was found practically filling the entire abdomen. It gave a sensation on palpation of a sac containing fluid under very high pressure. As far as could be made out by external palpation the lower margin of the tumour was situated 1½ inches above the symphysis pubis. It extended laterally into each flank and seemed to originate from the liver. Examination of the blood showed a slight leucocytosis. Examination of the fæces showed the presence of ankylostoma and ascaris ova. His general condition was wretched in the extreme. (Fig. 2.) I operated upon him on Dec. 11th, the procedure in every respect being the same as that carried out in Case 1.

His recovery has been quite uneventful, and at the present date he is completely cured (Jan. 21st, 1915). His general condition has marvellously improved. (Fig. 3.)

He received ½ grain emetine hydrochlor. daily for three weeks by hypodermic injection.

I think it remarkable to have had under my care two such extraordinary cases within a few days of each other. The similarity of the history in each case is worthy of note. The rapidity of recovery and almost immediate improvement shown after operation, the total absence of subsequent complications, demonstrate, I think, that liver abscesses even of very great dimensions offer every hope of recovery.

The total absence of jaundice in both cases indicates that the functions of the liver, so far as the production and secretion of bile were concerned, were at no time interfered with, though the area of active and healthy liver must have been extremely small.

Taiping, Perak, Federated Malay States.

CEREBRO-SPINAL FEVER AND THE SPHENOIDAL SINUS.

BY DENNIS EMBLETON, M.A., M.B. CANTAB.,
MAJOR, R.A.M.C. (T.); BACTERIOLOGIST TO NETLEY HOSPITAL;

AND

E. A. PETERS, M.D. CANTAB., F.R.C.S. ENG.,
CAPTAIN, R.A.M.C. (TEMP.); NOSE, THROAT, AND EAR SPECIALIST TO NETLEY HOSPITAL.

(*Preliminary Article.*)

WE bring forward the following cases to show that empyema of the sphenoidal sinus has a relation, and probably a causal relation, to the infection of cerebro-spinal fever. The spread of epidemic cerebro-spinal meningitis was originally considered to be different from that of other bacterial infections, such as cholera and plague. It did not appear to start from a definite focus, and no traceable series of links could be discovered between cases. It has now been shown that the bacterial infection spreads from person to person, giving rise to a rhinitis, similar to that produced by other "influenza cold" organisms. Of the infected people a very small percentage subsequently develop meningitis. What determines the onset of meningitis, or the resolution of the rhinitis, has not been ascertained. It has been regarded as being due to a variation in the virulence of the organism or difference in the resistance of the individual. It seems important in this connexion to establish the path by which the meningococcus gains access to the meninges from the naso-pharynx. There are two possible routes: (1) By the blood stream, and (2) by the lymphatics.

With regard to the blood stream route, it seems probable that the meningococcus very early gains access to the blood, as do all micro-organisms in bacterial infections. That the organism has been demonstrated in the blood and urine of people suffering from the disease is not important in this connexion, since the organism could as readily have obtained access to the blood from the cerebro-spinal fluid as from the nasal mucosa. What is of importance is that the organism has been demonstrated in the urine of people carrying the micro-organism in the naso-pharynx, and yet having no symptoms of meningitis. The organism, to appear in the urine, must have circulated in the blood stream. So it is possible that the organisms may gain access to the meninges *viâ* the blood stream.

With respect to the route by the lymphatics direct from the naso-pharynx, we would bring forward the following points which we believe support this path of infection.

Post-mortem Examinations of Three Fatal Cases of Cerebro-spinal Meningitis.

CASE 1.—Naso-pharyngeal mucous membrane very swollen and rugous. Sphenoidal mucous membrane injected; cavity full of glairy pus; ostia impervious to a probe. Osteitis of bone surrounding sinus; numerous pus cells present. No organism seen or cultivated from the bone. Deep congestion of the inner table of the skull; in the region of the sinus the dura mater injected; thick purulent lymph lying on the surface of the dura mater.

CASE 2.—The same findings, but the meningococcus was readily demonstrated in both the pus cells in the sphenoidal sinus and the bone.

CASE 3.—The same findings, but in addition the organism was demonstrated in the cancellous bone, in which the inflammation was much more extensive and reached to the apex of the petrous bone.

In none of these cases was there any inflammation occurring in the cribriform plate, the ethmoidal, frontal sinus, or the middle ears. The findings suggest that the meningococcus infection spreads from the naso-pharyngeal mucous membrane into the sphenoidal sinus. The opening of the sinus is then obstructed by the swelling of the mucous membrane, which is very liable to excessive swelling in children and adolescents in the course of inflammation. The occlusion would be favoured by any abnormal contraction of the ostia or pathological change. Subsequently to empyema of the sinus infection of the dura mater may supervene. So it might be suggested that among the contacts who have a mucosa infection, it is those who develop an empyema of the sphenoidal sinus who develop cerebro-spinal meningitis. It is accepted that a drop or two of pus in the sphenoidal sinus may cause death (Sir StClair Thomson), while the operation establishing drainage is not a serious procedure.

Fatal cases of sphenoidal sinus empyema usually develop cavernous thrombosis, clinically evident by proptosis of the eyes. In these cases the organisms present cause thrombosis. On the other hand, when the meningococcus infects the sinus with an empyema thrombosis does not occur, and the meningococcus infects the meninges. The headache of cerebro-spinal fever is frequently referred to the occipital region, to which the pain of sphenoidal empyema or manipulation is also referred.

Clinically the carriers fall into two classes, typical examples of which are given: (1) Acute, lasting about three weeks; and (2) chronic.

CLASS 1.—Private ——, a Canadian, who yielded practically a pure cultivation of meningococci from his naso-pharynx. The mucous membrane of the nose and naso-pharynx was swollen and red, and exuded a clear profuse discharge. The ostia of the sphenoidal sinus were not located by a probe. Ung. hyd. nit. dil. ʒ ss., menthol gr. v., ol. olivæ ad ℥ i. was painted into the nostrils, and the tonsils were swabbed with lot. hydrogen. peroxidi. In three weeks a swab proved negative. The acute carrier may pass on to Class 2.

CLASS 2.—The chronic carrier does not exhibit the acute congestion of the nasal mucous membrane, and the organism is not always found, suggesting the presence of a reservoir which leaks from time to time. Case W. I. is an instance of this condition. Though the patient was actually suffering from the disease the same clinical conditions appeared on rhinoscopic examination.

Three healed cases of cerebro-spinal fever were admitted from Tréport Stationary Hospital, and one of us (E. A. P.) examined them. The mucous membrane of the nose and naso-pharynx was pale, dry, and shrunken. Nasal obstruction in one case prevented location of the sphenoidal ostia, but in the other two the ostia were unusually patent, so that an empyema was almost impossible. It is credible that these men owed their recovery to this patency.

With these data in hand one of us (E. A. P.) proceeded to drain the sphenoidal sinus in Case W. I. (referred to above).

An Extract from the Notes of Lieutenant J. S. ROWLANDS, R.A.M.C., *of the Welsh Hospital.*

CASE W. I.—Aged 17, North Irish Horse, landed at Havre August 21st, 1914. December: Bad cold; slight hæmorrhage from the lung. Jan. 17th: Rouen; tubercle diagnosed. Feb. 14th: Admitted to Welsh Hospital, Netley, with "rheumatic" pains; apparent recovery. 23rd: When up and about temperature rose to 104° F. (A cerebro-spinal carrier was subsequently discovered in the patient who occupied the opposite bed.) 24th: Severe frontal headache; erythematous rash; pain at back of neck. 25th: Definite meningeal symptoms; increased reflexes; Kernig's sign present. Lumbar puncture revealed cerebro-spinal fluid under pressure containing pus cells. No organisms discovered. (Mr. B. G. Klein's report.) 25 c.c. of serum were injected. 28th: Meningococci grown from cerebro-spinal fluid. March 6th: Patient has had in all eight injections of serum after lumbar puncture. Head still retracted. 7th: No growth from cerebro-spinal fluid. 9th: Relapse; naso-pharyngeal swab negative. 10th: Autogenous vaccine (5 millions) prepared by Mr. Klein were injected by Lieutenant Rowlands hypodermically. 12th: Soamin 5 gr. injected intramuscularly. 13th: Cyanosis. 17th: Twitching; dusky hue; incontinence of urine; no growth from cerebro-spinal fluid. 20th: Improvement and lower temperature. 21st: Another relapse. Lumbar puncture without serum injection. 25th: Meningococci in naso-pharynx. April 2nd: Meningococci not found in naso-pharynx. 3rd: Pulse 110–120; generally better; occasional delirium. 4th: Worse; lumbar puncture and serum. 7th: Meningococci not found. 14th: Meningococci were found in the naso-pharynx. Nasal treatment with ung. hyd. nit. dil. ʒss., menthol gr. v., ol. olivæ ad ℥i.—painted into the nose. 16th: Urotropin given; pulse 110. 30th: Transferred to Royal Victoria Hospital on concentration of cerebro-spinal cases. Up to this time 17 injections of serum have been given, but relapses still occur. May 3rd: Chloroform was given by Lieutenant G. C. Adeney, R.A.M.C., and the sphenoidal sinus opened from the nose by one of us (E. A. P.); a drachm of pus escaped from the left sinus. Neither ostium could be found with the probe, so the thin bone was broken down with Heath's small mastoid burr. Meningococci were found in the glairy pus.

Subsequent history.—The patient was rather better from the first day. There is now no retraction of the head and Kernig's sign is only slightly present, but the pulse keeps up to 115–125. May 7th: Temperature again up to 101°. May 16th: During the last week patient has done well; eats and sleeps well; control of evacuations. Temperature up to 100° on one occasion; Kernig present. Speech coherent. The sphenoidal sinuses are washed out daily.

Conclusions.

1. Sphenoidal empyema is associated with cerebro-spinal fever in a causal manner.
2. Cerebro-spinal fever is a meningitis due to organisms entering the meninges from the sphenoidal sinus by way of the lymphatics.
3. Adults are less susceptible owing to a diminished tendency to sphenoidal empyema, as they are not prone to excessive swelling of the mucous membrane and so to closure of the ostia, as is seen in adolescents.

It may be advisable to open the sphenoidal sinus in all cases of cerebro-spinal fever; it is certainly advisable to treat the naso-pharynx on the lines used for the acute carrier (Class 1, *ante*).

We would define this paper as a plea for nasal hygiene in the case of recruits.

We beg to acknowledge our indebtedness to Colonel T. C. Lucas, R.A.M.C., Officer Commanding Royal Victoria Hospital, and to Lieutenant-Colonel William Sheen, Officer Commanding Welsh Hospital.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.—The annual general meeting of this society will be held at the offices of the society, 32, Craven-street, Strand, London, W.C., on Wednesday, May 26th, at 4 P.M., to receive and adopt the annual report and balance sheet and to elect officers.

GIFT TO NAIRN HOSPITAL.—In memory of her late husband, Captain Ewan James Brodie, of Lethen, of the Cameron Highlanders, who was killed in action at the battle of Ypres, on Nov. 11th, 1914, Mrs. Brodie, of Lethen, Nairnshire, has given to the Nairn Town and County Hospital the sum of £1000 to endow a bed, to be called the Lethen Bed. The gift has been gratefully accepted by the directors of the hospital.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Osteotomy of the Tibiæ.—Self-mutilation of the Penis in Boys.

A MEETING of this section was held on May 14th, Mr. J. CHARTERS SYMONDS, the President, being in the chair.

Mr. T. H. KELLOCK showed a case of Double Osteotomy of the Tibiæ ten years after operation. The patient was a boy now aged 13 years. When 3 years of age his tibiæ were badly deformed and much bowed outwards and forwards; there was a separation of the internal condyles of the femora, when the malleoli were touching, of 3 inches. Open osteotomy of the tibiæ was performed, the fibulæ fractured, and the legs put up in plaster-of-Paris splints. At the meeting the legs were seen to be quite straight, and in the skiagram there was practically no indication of the site of the osteotomies, the line of the bone being normal. The boy was again in hospital for abdominal trouble—probably tuberculous peritonitis.

Mr. KELLOCK also read a short paper on a form of Self-mutilation of the Penis in young boys. After referring to the case of a boy, aged 8, from whom he had removed a metal ring which surrounded the glans and had ulcerated through the floor of the urethra, and to another in which cotton had been twisted round the base of the glans, he said that during the last few years he had met with three other somewhat similar cases. In each of these hair had been twisted round the penis just behind the glans. The last was typical of all three. It was that of a boy aged 5. He had been circumcised at the age of 3, after which ulceration had occurred behind the glans. Eighteen months before he had come under Mr. Kellock's observation the mother had found a piece of hair hanging round the penis. For a few weeks the urine had been passed through an opening under that organ. The glans was almost completely separated and the urethra was quite divided. The glans was attached by an isthmus only one-eighth of an inch in diameter, and was much discoloured. Immediately behind the corona was a circular sulcus which was completely covered by epithelium. Under an anæsthetic, by using a crochet needle, a hair was found twisted three times round the narrow isthmus. The history and condition of the other two cases were practically the same. The treatment by plastic operation after removal of the hair was one of no little difficulty. In two he had been able to reconstruct the urethra; in the third operation had been followed by sloughing off of the glans.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

Exhibition of Cases and Specimens.—Infundibulin in Primary Uterine Inertia and in the Induction of Labour.—Complete Inversion of the Vagina.—Diphtheritic Stenosis of the Vagina.—So-called True Hermaphroditism.

A MEETING of this section was held on May 6th, Dr. W. S. A. GRIFFITH, the President, being in the chair.

Dr. J. BRIGHT BANISTER showed: (1) A Twisted Omentum, simulating twisted ovarian cyst; and (2) Placental Attachment to Fœtal Head.

Mr. T. G. STEVENS showed a specimen of Rhabdomyoma of the Vulva. The tumour was of the size of a small orange, and had existed and slowly enlarged for the past three years. It was situated at the posterior part of the labium majus and was not pedunculated. The skin over it was thinned and on the point of breaking. Microscopically, the tumour is composed of a delicate fibrillated stroma, enclosing elongated masses of protoplasm with oval nuclei, but no very clearly defined cell outlines. The general appearance of these protoplasmic masses is that of immature striated muscle. There is some longitudinal striation to be seen, but no transverse striation can be demonstrated. The stroma in parts is degenerate and shows some liquefaction and minute cyst formation. The tumour is encapsuled and shows no evidence of malignancy.—Remarks were made by Dr. HERBERT SPENCER, Dr. CUTHBERT LOCKYER, and Dr. W. BLAIR BELL.—Mr. STEVENS replied.

Mr. W. Gilliatt showed the Viscera from a fatal case of Eclampsia.

Dr. C. E. Purslow demonstrated a case of Tubal Pregnancy showing Fœtus undergoing Dissolution. The specimen was removed by abdominal section from a married multipara aged 31 years. Menstruation had been regular until 12 weeks before admission to hospital. Amenorrhœa then set in, and continued until a fortnight before admission, since which time there had been continuous slight loss. There had been two typical attacks of pain with faintness. On examination there was a well-marked tumour in the left iliac region. This was diagnosed as a tubal pregnancy, but the physical signs were unusual in that the swelling was entirely above the pelvic brim and could not be reached by the finger either in the vagina or the rectum. The specimen showed the unruptured distended tube. Cross sections had been made, and these showed a diameter of 2¼ inches. The tube was filled with firm blood clot, in the centre of which was an amnial cavity containing turbid fluid, and in this was found the macerated head of a fœtus of about ten weeks' development; no other part of the fœtus could be found. The specimen was interesting as showing that a fœtus as far advanced as this could macerate and disappear in the liquor amnii.

Dr. Blair Bell read a short communication on Infundibulin in Primary Uterine Inertia and in the Induction of Labour. It was pointed out that infundibulin, introduced by Dr Bell in 1909, had established its place in obstetrics owing to its power of promoting and augmenting rhythmical contractions during and after parturition. Dr. Bell now called attention to the fact that although the induction of labour could rarely be effected by administration of infundibulin alone, yet this extract had the power of sensitising the uterus before labour; consequently the administration of infundibulin in conjunction with other mechanical measures, such as the insertion of a pack or of bougies, led to certain and rapid induction of labour. In this connexion a case of placenta prævia, in which serious bleeding occurred in the eighth month, was mentioned. The cervix was packed with gauze, and infundibulin was injected with an excellent result. The great value of infundibulin in primary uterine inertia also was emphasised. It was pointed out that this was as noticeable when the inertia was diagnosed before labour commenced as during labour. In the former circumstances the uterus could be sensitised and its tone improved during the last two weeks of gestation, and an interesting case was quoted by way of illustration.—The President, Dr. R. Drummond Maxwell, Dr. J. P. Hedley, Dr. Hubert Roberts, Dr. G. Drummond Robinson, and Dr. Purslow discussed the paper, and Dr. Blair Bell replied.

Mr. Douglas Drew read a short communication on Complete Inversion of the Vagina after Hysterectomy associated with Vesical Calculus. A patient, aged 53 years, had undergone a total hysterectomy for fibroids 12 years previously. Within a year of the above operation the vagina became completely inverted. The condition had not been treated for the past ten years. A large calculus was removed by suprapubic cystotomy, and the prolapse was treated by Le Fort's operation and colpoperineorrhaphy.

Dr. Drummond Maxwell read a short communication on Diphtheritic Stenosis of the Vagina.—Remarks were made by the President and Dr. Spencer.

Dr. Blair Bell read a paper on So-called True Hermaphroditism. The meaning of "true hermaphroditism," so far as man is concerned, was first discussed, and contrasted with the phenomenon seen in invertebrates. A complete classification of hermaphroditism in all its varieties was given to illustrate the biological importance of the condition. It was pointed out that the so-called "true hermaphroditism" in man should be termed "glandular partial hermaphroditism." All the really authentic cases (probably four in number, apart from Dr. Bell's case) have had ovo-testes. Many of the recorded cases of "true hermaphroditism" had been disproved, and this specially applied to those cases in which a separate ovary and testis had been recorded. Further, all the cases with ovo-testes had shown predominating feminine characteristics. Dr. Bell's case was that of a patient who had presented all the characteristics of femininity, with regular menstruation, until 18 months after puberty, when menstruation ceased and masculine characteristics developed; these included a bass voice and an excessive growth of hair on the body with masculine distribution. At first a diagnosis of suprarenal hyperplasia was made, and the patient was treated with ovarian and thyroid extracts. Later laparotomy was performed, and sections were removed from both gonades. The left had the macroscopic appearance of a testis. The pathologist, however, reported that the left gonad was the seat of columnar carcinoma. Consequently the abdomen was reopened, and the gonades, tubes, and fundus uteri were removed. On examining the sections Dr. Bell came to the conclusion that the left gonad was an ovo-testis and not the seat of a malignant growth. The patient was therefore a glandular partial hermaphrodite. The histological appearances were fully discussed, and the relation of ovo-testes to the normal development of the gonades was considered. Finally, criteria determining glandular partial hermaphroditism were suggested.

LARYNGOLOGICAL SECTION.

Annual General Meeting.—Exhibition of Cases and Specimens.—Cases of Warfare Injuries and Neuroses.

The annual general meeting of the above section was held on May 7th, Dr. G. William Hill, the President, being in the chair.

Dr. J. A. M. Broeckaert, of Ghent, ex-President of the Belgium Society of Oto-rhino-laryngology, was unanimously elected a corresponding member of the section.

The following cases and specimens were shown:

The President: A man, aged 55 years, in whom a Malignant Tumour at the base of the tongue had entirely disappeared after treatment with radium needles.

Mr. W. M. Mollison: A case for diagnosis.

Dr. J. Dundas Grant: A patient with Deformity of the Nose improved by a submucous resection of the nasal septum.

Dr. Irwin Moore: 1. A boy from whom a Naso-pharyngeal Fibroma had been removed through the mouth without any preliminary operation. 2. A man with a Growth of the Antrum extending into the Naso-pharynx. 3. A patient with Malignant Stricture of the Œsophagus who had been successfully treated with a Hill's tube for a period of nearly six months.

Mr. W. Stuart-Low: A patient suffering from Recurrent Columnar-celled Carcinoma of the Antrum.

Dr. Frederick Spicer: A case suffering from a new growth in the post-nasal space.

Dr. W. H. Jewell: A specimen showing a Halfpenny impacted in the Œsophagus.

Mr. W. Douglas Harmer: An old man with a Pharyngeal Fistula which had appeared after an incision of an abscess in the neck.

Sir William Milligan read a paper giving a description of the cases of Warfare Injuries and Neuroses treated at the 2nd Western Military Hospital. This was supplemented by a demonstration of X ray photographs by Mr. F. H. Westmacott.—Patients who had been injured in the war were shown by the President (2), Mr. Herbert Tilley (3), Dr. J. Coubro Potter (1), Mr. J. F. O'Malley (5), Mr. Walter G. Howarth (1), Sir StClair Thomson (2), Mr. G. H. L. Whale (10), and Mr. Stuart-Low (1). A general discussion of the subject was held, in which the following joined: The President, Sir Felix Semon, Dr. W. J. Horne, Sir StClair Thomson, Mr. Tilley, Dr. Dundas Grant, Mr. Stuart-Low, Mr. E. D. D. Davis, Dr. Coubro Potter, and Mr. O'Malley.—Sir William Milligan and Mr. Westmacott replied.

MEDICAL SOCIETY OF LONDON.

Exhibition of Early Books on Naval and Military Surgery and other Objects of Medical and Surgical Interest.

The annual general meeting of this society was held on May 10th, Sir J. Bland-Sutton, the President, being in the chair.

Mr. D'Arcy Power gave a short demonstration illustrated by the epidiascope on Early Books on Naval and Military Surgery from the society's library. He prefaced his demonstration by exhibiting a silver coin which had been lent to him for the purpose by Mr. Laurie Lawrence, F.R.C.S. Eng. The coin was a silver penny struck in the reign of Henry III.

by Thomas at London. The interest of the coin lay in the fact that *Thomas of Weseham* who struck the coin was the first serjeant-surgeon of whom anything is known. He had property in Coleman-street and was steward of the forest of Cannock. In 1260 the King granted him a die to mint with. The coin shown was one of three specimens found a few years ago at Brussels amongst a hoard of 100,000 pennies struck in the reign of Henry III. It was of the type minted between 1260 and 1270.

A portrait of *John Arderne* was then shown. He was born in 1307 and lived to a good old age. It was possible that he was at the battle of Crécy. It is certain that he was on terms of intimacy with many of the heroes whose deeds are told in Froissart.

There is no known picture of *William Clowes*, but his autograph was shown by the kindness of Dr. F. W. Cock, F.S.A. Clowes served in Flanders with the Earl of Leicester in 1583 and in the fleet against the Armada in 1588. He was a surgeon to St. Bartholomew's Hospital. His book "De Morbo Gallico" was shown.

A portrait of *John Woodall* (1569–1643) was exhibited, and with it a copy of his great book on surgery, "The Surgeon's Mate." He says that he was a poor man who had travelled extensively in France, Germany, and Poland. He settled in London during the Great Plague of 1603, and was afterwards appointed surgeon-general to the East India Company. His book served for many years as the text-book of naval surgery.

Richard Wiseman was shown to be a delicate-looking man who was born about 1621. He entered the Dutch Naval Service, but in the Civil War he became personally attached to Charles I. His chirurgical treatises were models of surgical literature.

John Ranby (1703–1773) is interesting as being the last serjeant-surgeon who accompanied his Royal master on active service. He was present with George II. at the battle of Dettingen in 1743. He wrote a tract on "The Method of Treating Gunshot Wounds," which set the fashion for many subsequent years. It is interesting now because he foreshadowed that associated aid for the wounded which has only recently been adopted by the formation of the Royal Army Medical Corps.

George James Guthrie (1785–1856) was the great surgeon of the Peninsular War in its later phases. He was appointed assistant surgeon to the Twenty-ninth Regiment when he was only 16 years of age, his colonel being 24 years old. Yet in spite of their youth the regiment was said to be the best led and the best doctored in the service. Guthrie's claim to recollection was that he taught assiduously that the large arteries were capable of digital compression. It was not necessary, therefore, to tie them in their continuity before operating, as had hitherto been the practice of military surgeons. He also taught that both ends of a wounded artery must be tied.

HARVEIAN SOCIETY OF LONDON.—A meeting of this society was held on May 13th, Dr. G. de B. Turtle, acting President, being in the chair.—The following cases were shown:—Dr. W. H. Willcox: Sarcoma of the Peritoneum in a man aged 29.—Dr. Graham Little: Two cases of Dercum's Disease; the lipomata were roughly symmetrical along the courses of nerves and in one case distinctly tender. —Mr. V. Z. Cope: Case for diagnosis of an excrescence on the leg.—Mr. Kenneth A. Lees: 1. Fractured Base in a girl in whom cranial nerve paralysis had occurred some days after the initial lesion. Taste was lost over the anterior two-thirds of one side of the tongue. 2. Sarcoma of the Thigh. 3. Cervical Rib.—Dr. F. S. Langmead: Graves's Disease in a girl aged 11.—The cases were discussed by the President, Dr. Graham Little, Mr. Cope, Mr. Lees, and Dr. Langmead.

THE NURSING OF TUBERCULOUS PATIENTS.—The Local Government Board have expressed their willingness to consider applications from councils for the employment of dispensary nurses who may have sufficient time to undertake the nursing of tuberculous patients in their own homes. When the needs of the army no longer preclude it, permission will be considered for the employment of additional nurses, either direct or by arrangements with voluntary nursing associations.

Reviews and Notices of Books.

Infant Mortality.

By HUGH T. ASHBY, B.A., M.D. Camb. Cambridge: The University Press. 1915. Pp. 229. Price 10*s.* 6*d.* net.

THIS recent addition to the Cambridge Public Health Series is a painstaking digest of the vast literature on the subject of infant mortality which has of late years accumulated through the labours of our Government and public health departments, and the deliberations of both national and international conferences. The mere reading of this literature is a serious undertaking; the epitomising of its main results in a form which can be understood by that large section of the public which is now beginning to take an interest in the subject is, indeed, a task before which the most courageous might well hesitate. On the whole, Dr. Ashby has done his work exceedingly well and has given fair and unprejudiced acknowledgment to the several factors which have contributed towards the great fall in the mortality rate among infants which the last ten years have witnessed in this country. The author clearly shows that the most important element in the successful rearing of infants is the intelligent coöperation of the mother, and that good housing and sanitary conditions are contributory factors of great significance.

In dealing with the special causes of infant mortality Dr. Ashby classifies them into three groups: (1) Preventable causes; (2) partially preventable causes; and (3) non-preventable causes. Of the preventable causes diarrhœa is described as the one which causes the largest number of deaths. It is strange that while due emphasis is given to the part which micro-organisms, improper feeding, and chill play in the etiology of this devastating disorder, practically no mention is made of the influence of heat. This question was to have been the chief subject for discussion at the International Conference on Infant Mortality, which would have been held in London this summer had not the war interfered with the arrangements. As causative factors considerable prominence is given to the house fly and the use of condensed as well as unboiled milk.

In discussing the ways by which infant mortality can be lowered the author states that the development of the infant depends on the following factors: (1) Inheritance, (2) environment, and (3) food. He says little can be expected from the side of eugenics except by trying to prevent those marrying who are physically unfit. It is curious that food should be regarded as something apart from environment. And again, there is something almost paradoxical in the view, which Dr. Ashby holds in common with many other authorities, that nurture as opposed to nature begins to take effect at the moment of conception—that is to say, that the hereditary factor is all-important up to the moment that the germ cell and the sperm cell fuse together into one organisation, and that from that moment congenital influence or maternal nurture begins to take effect. Are not the two parental cells subject to the influence of nurture before fusion? Or, in other words, is not what is generally called the hereditary factor also in some degree controllable?

Dr. Ashby regards the part which the official health visitor is likely to play in the prevention of infant mortality as the most hopeful of all those means which have so far been tried. He devotes some space to an account of the available facilities for training, and while giving full acknowledgment to the value of the amateur and voluntary health worker, he appears to think that they will not play so important a part in the future as they have in the past.

Differential Diagnosis, presented through an Analysis of Cases.

By R. C. CABOT, M.D., Assistant Professor of Clinical Medicine, Harvard University Medical School, Boston. Vol. I., pp. 764, 193 illustrations, 385 cases (Third edition). Vol. II., pp. 710, 254 illustrations, 317 cases. London and Philadelphia: W. B. Saunders Company. 1915. Price 24*s*. net.

THE method of teaching medicine by the description and discussion of individual cases of disease is both admirable and time-honoured. It dates, at any rate, from the days of Hippocrates, whose seven books, *De Morbis Vulgaribus*, contain records of numerous illustrative cases. The method was brought to a very high pitch of perfection in Morgagni's epoch-making two folios, *De Sedibus et Causis Morborum*, published at Venice in 1761, wherein especial stress was laid on the morbid anatomy of disease as illustrated by some 640 carefully conducted post-mortem examinations. The same method, developed from the point of view of the differential diagnosis of disease, is employed in Dr. Cabot's book now before us.

The first half of Vol. I., now in its third edition, appeared first in 1911, and is concerned with the diagnostic significance of pain in various parts of the body, as illustrated by 212 case-histories; the second half of the volume is given to 11 chapters of case-histories illustrating fever, rigors, convulsions, coma, cough, and other such prominent signs or symptoms. Vol. II., now appearing for the first time, contains 19 more chapters, and in each is given a careful study of a further important sign or symptom. The chapters in each volume are preceded by a table showing the relative frequency of the commoner causes of each symptom, based on about 180,000 cases treated at the Massachusetts General Hospital during six recent years, and on statistical articles from the literature. Each case is presented in the form of a summary, often with a diagram of its physical signs and a reproduction of its hospital temperature chart; then follows a "discussion" of its diagnosis, and finally, a paragraph on its "outcome" and the diagnosis, or error of diagnosis, that was made. In the first volume the diagnosis is definitely stated, having a line to itself at the end of each case described. This arrangement catches the reader's eye very satisfactorily, but unfortunately is not adopted in the second volume, where the reader has to search for the true diagnosis in either the "discussion" or the "outcome," often a lengthy process, requiring the wasteful expenditure of mental energy.

Dr. Cabot has made an excellent choice of prominent symptoms for illustration, and his typical cases are valuable as dealing with the commoner diseases rather than with rarities. The descriptions are fully and clearly written, and, considered as problems in diagnosis, are often of great interest. Not a little interesting, too, is the type of disease that they show to be prevalent in the Boston Hospital. Lead poisoning, for example, seems to be fairly common among water-drinkers; to judge by the case-histories, chronic alcoholism seems to be common, yet Dr. Cabot remarks (Vol. II., p. 269) that next to pregnancy "nephritis is the commonest cause that I know for morning vomiting." Again, in his table of some 3500 cases of hæmoptysis, he has to record no cases of aortic valvular disease, congenital heart disease, bronchitis, or exophthalmic goitre, for example, a statement that merely proves how widely the signs shown by different patients in different countries, and recorded by different observers, may vary in any one disease.

The book is clearly written, and may be cordially recommended to senior students of medicine, and to medical practitioners who wish to exercise their diagnostic powers. As Dr. Cabot points out, incorrect diagnoses are usually due to failure to recognise the physical signs present; less often they result from the inability to think correctly. His book is calculated to stimulate the thinking faculties most effectively.

Dynamic Evolution.

By CASPER L. REDFIELD. London and New York: G. P. Putnam's Sons. 1914. Pp. 210. Price 6*s*. net.

THE author of this book attempts to found a theory of evolution and degeneration upon the principles of physics. The abundance of ideas and considerable originality which characterise the work are unfortunately accompanied, as so often happens, by deficient knowledge and study of the facts. Conclusions and generalisations are thrown promiscuously before the reader, supported by evidence which is literally worthless.

The author starts from the assumption that "in the organic world we find bodies having forms of energy peculiar to themselves, which energy acts to individualise the bodies with which it is associated." This proposition is contrary to the opinion of most physiologists, but Mr. Redfield does not apparently know that there is any problem at issue in his statement: his attitude is simply a naïve assumption without a second thought given to it. After discussing the evolution of trotting horses, he comes to man. His main proposition is that the mental capacity of an individual is dependent on the amount of mental work performed by his father before begetting him. Hence the most capable men were born when their fathers were comparatively elderly and had worked hard. The effects being cumulative, the greatest men of all are those whose grandfathers, as well as fathers, were advanced in life before having children. This conclusion having been attained by the most dubious imaginable chain of deductions is clinched by printing lists of distinguished men whose births are separated by more than the average interval from the births of their fathers and grandfathers. The author states that he has never been able to find out anyone of considerable eminence, with the exception of Jonathan Edwards, who was born less than 58 years after his paternal grandfather. Furthermore, the mental characteristics of men are alleged to be dependent on the age of their fathers at their conception. They are military and aggressive if their fathers were less than 31; artistic, musical, and literary, if their fathers were between 31 and 40; statesmen, if between 41 and 50; moralists and philosophers, if their fathers were over 51. Why then, we may ask, was John Stuart Mill born when his father was only 33, and Herbert Spencer when his father was only 30? How was it that the great Lord Chatham was only 55 years younger than his paternal grandfather? But it is superfluous to cite illustrations in disproof of a theory so inadequately supported as that before us.

Another of the author's most important theories is that longevity likewise is dependent on the age of the father when the child was born. The author reaches this result by the following deduction: cell-division becomes slower as age advances; an elderly father, whose cell-division is slow, will produce a son whose cell-division is also slow; that son will therefore live long. And once again the argument is finished by the crudest possible statistics, which as set forth are quite powerless to prove anything at all, far less the conclusion desired by the author. Before Mr. Redfield attempts another book he should curb his imagination by contact with facts; we have here a raw collection of impulsive and untested ideas.

Malay Poisons and Charm Cures.

By JOHN D. GIMLETTE, M.R.C.S., L.R.C.P. Lond., Residency Surgeon of Kelantan. London: J. and A. Churchill. 1915. Pp. 127. Price 3*s*. 6*d*. net.

THE Malay States are but little known to any but extensive travellers, but they are a most interesting country from many points of view, whether we consider their anthropology, zoology, botany, or geology. The main subject of Mr. Gimlette's little book—namely, Malay medicines and poisons—is, as he says in his preface, of special scientific interest, and presents a large field for medical research.

As in all primitive countries medicine among the Malays is largely mingled with magic and charms, and Mr. Gimlette's first chapter is devoted to an account of the Malay "medicine man," who is called "bomor." It is curious to note the survival of ancient Greek philosophy in the modern philosophy of the Malay bomor, whose belief is given on p. 5 as follows: "According to the Kelantan bomor, disease is sent by God, and it springs from the elements, fire, air, earth, and water." Compare with this Plato in the Timaeus, cap. 82: "Now everyone can see whence diseases arise. There are four natures out of which the body is compacted, earth and fire, and water and air, and the unnatural excess and defect of these ...... produce diseases and disorders."[1] In the Kelantan belief, the elements have spirits (jinn) associated with them, and every human being has in addition an internal jinn peculiar to himself, without whose coöperation the external jinn of the element is powerless. Seeing that the Malays are Mohammedans the elemental doctrine probably reached them by way of Galen and the mediæval Arabic physicians. Diseases are held to become more powerful when the thought of man is fixed upon the symptoms, a doctrine which, as Mr. Gimlette reminds his readers, is in some way comparable to "Christian Science." Charms and spells are important adjuvants to the operation of medicines, and the author gives a selection, some translated and some, in an appendix, in the original.

Of the poisons mentioned in the book a good many are used as medicines—for instance, datura, opium, and arsenic. Of poisons used as such a certain number probably act solely as mechanical irritants, such as bamboo hairs, fish spines, and the bristles of a sea worm, though in the two animal products there is presumably some inherent poisonous substance, as is the case with the spines of the weaver fish of our own coasts. The bristles of hairy caterpillars are also administered as irritants. Most of the vegetable poisons are of the paralytic intoxicant type, but some cause choleraic symptoms, and some are applied to the skin to cause acute dermatitis. It is interesting to find that Malay poisoners hold the tradition of the poison which will kill at any distance of time according to the dose. "It is said that an accomplished Malay criminal can give a single dose of poison and time the death of his victim within three months, six months, or even three years, according to the dose and particular combination he uses." Mr. Gimlette adds that no clinical case of this practice has come under his own observation. The same tradition exists in Persia to this day, and it was commonly told of the sixteenth and seventeenth century Italian poisoners; but, though it would seem that so universal a tradition must have some foundation, no such poison is, so far as we know, known to science.

Mr. Gimlette modestly says that the ground of the field of medical research on the subject of Malay poisons is hardly broken in his book. He has, however, given us enough to make us express the hope that he will continue his tilling.

LIBRARY TABLE.

Paris Waits: 1914. By M. E. CLARKE. London: Smith, Elder, and Co. 1915. Pp. 289. Price 5*s*. net.—This little book is made up of a series of articles dealing for the most part with life in Paris from just after the declaration of war until the return of the Government from Bordeaux. Some of the chapters, however, deal with other places, such as Senlis, Meaux, and Orleans. Miss Clarke is a vivid and yet quite simple writer, and her descriptions of the psychology of Paris during the most anxious time are extraordinarily interesting. Of individual cases Miss Clarke relates a very striking one of a Parisian "who was well known to be among the most neurasthenic of Parisians. Nothing pleased him for more than five minutes, and he spent his days in grumbling, taking scented baths, dabbling in the arts, and trying on new clothes." He was called up for service, went to the front, became ill, and was sent back for treatment, and his one idea was to get back to service. And, as his sister said to Miss Clarke, "You should see him now. He refuses to shave, he thinks baths are superfluous, and we had to have a private dining-room in the hotel when he left the hospital because he refused to use a knife and fork. He says they complicate existence, and he told his wife she did too. C'est épatant, because, you see, if he has to go back it is much better that he should go feeling like that. He will be safer and we shall be less unhappy." If the reader wants a real thrill let him read the experience of the British Flying Corps mechanics related on p. 84, which recalls our youthful feelings on reading the escape of Monte Cristo. If the "seventeenth century prophecy" quoted on p. 113 *et seq* is authenticated it is certainly sufficiently amazing.

La Pratique Héliothérapeutique. By le Dr. JAUBERT (d'Hyères). Paris: Baillière et Fils. 1915. Pp. 96. Price 1.50 francs.—This is a small book of practical details regarding the use of the sun's rays in therapeutics; the theoretical side of the subject is touched upon only so far as it helps to explain the reason for the various modifications adopted in practice. The author has a very strong belief in the value of the sun bath in the convalescent stage, while also considering it an important adjunct to other therapeutic measures in cases of gout, rheumatism, diabetes, and nephritis. Many forms of arthritis, including tuberculous affections, are benefited by it materially, and the method seems to be particularly valuable for children and young subjects generally. To practitioners in this country the volume is of value chiefly as indicating a line of treatment for obstinate cases where the patient's circumstances allow of a visit to places abroad that are more abundantly supplied with sunlight.

---

[1] Jowett's Translation.

The Pharmaceutical Pocket-book for Practitioners and Students. Edited by JOHN HUMPHREY, Ph.C., F.J.I. Fifth edition. London: Pharmaceutical Press. 1915. Pp. 360. Price 1s. 6*d.* net.—The fifth edition of this pocket-book will probably be of service to pharmacists rather than to members of the medical profession, although the latter will find it of use as a book of reference. For example, it contains valuable details relating to the schedule of poisons and to the sale of poisons in Great Britain, two subjects which are frequently mentioned in coroners' courts. Some trouble has been taken to convert the metric formulæ of the British Pharmacopœia into their equivalent imperial quantities. A comparison of the two columns is a sufficient justification of the adoption of the metric system—for example, it is interesting to compare the round numbers of decoctum aloes compositum with the awkward fractions of the imperial system. A section deals with the art of dispensing of doses and official medicaments, and a tabular statement is given of the materia medica of vegetable and animal origin. After details concerning equivalents and measures of length, mass and capacity, and of thermometric equivalents, various analytical data are appended dealing with the analysis of water, of milk, and of urine. It is interesting to find that nearly 80 pages are devoted to a dictionary of synonyms; happily most of these are not officially recognised. The section relating to the treatment of poisons is too concise.

JOURNALS AND MAGAZINES.

Annales de l'Institut Pasteur, April, 1915.—The diagnosis of tuberculosis by reactions in the serum is still in the experimental stage, and in view of the practical importance of the subject any carefully controlled researches which seem to promise a clinical application are of special interest. In this issue MM. E. Debains and F. Jupille record their observations upon a complement-fixation test which in their hands has afforded satisfactory results. They suggest that the difficulty found by previous workers has been in obtaining a satisfactory antigen, since that obtained from cultures of the tubercle bacillus upon a glycerin-peptone medium is variable. MM. Calmette and Massol found that a more satisfactory antigen was obtained by maceration of the bacillary bodies in peptone water; indeed, with such an antigen they obtained 92·5 per cent. of positive reactions in 134 serums from human tuberculous patients examined by the Bordet-Gengou method. MM. Debains and Jupille have, however, employed a different antigen—viz., Besredka's tuberculin obtained by growing the tubercle bacillus upon an egg-bouillon medium. They have rejected other antigens because they have found some of them inconstant in their action, while others have proved to be hæmolytic in the presence of normal serums, although by themselves they might not exert any action upon a hæmolytic system. The method they adopt is to employ a fixed dose of the antigen and to vary the quantity of complement. The intensity of the reaction is determined by measuring the increasing doses of the complement, previously diluted and titrated, which the serum to be examined can fix in the presence of the antigen. They first titrate the complement, using a dilution of 1 in 30, with at least two separate normal serums. The actual method of carrying out the reaction consists in placing 0·2 c.c. of the serum to be tested (previously heated to 56° C. to inactivate it) in each of five test tubes. To all but one of these 0·3 c.c. of the antigen, previously titrated, is then added, and to all of them certain measured quantities of the diluted complement and of saline solution. After half an hour at laboratory temperature and an hour in the incubator 0·1 c.c. of the hæmolytic amboceptor and 0·1 c.c. of a 20 per cent. suspension of washed red corpuscles are added to each tube, and all are replaced in the incubator for half an hour. They are then kept at the laboratory temperature for 20 minutes and read off. The results are recorded as positive, negative, or partially positive. The tube to which no antigen is added is a control to demonstrate that the serum examined is not anti-hæmolytic by itself. It is essential to control the reaction with at least two normal serums. MM. Debains and Jupille have found that serums which give a very strong positive Wassermann reaction are capable of fixing complement in the presence of Besredka's tuberculin, which they explain by supposing that the lipoids of the yolk of egg modified by the culture of the tubercle bacillus act as a syphilitic antigen. It is therefore advisable to do a Wassermann reaction at the same time as the tuberculous reaction. The authors have studied the blood of 610 persons, of whom 580 were examined clinically. The general summary of their results shows that of 59 patients suffering from pulmonary tuberculosis in the second and third stages with poor general condition 81·3 per cent. gave a positive reaction, of 95 patients in the first and second stages in good general condition 90·3 per cent. were positive, and in 61 cases with localised or doubtful signs 93·4 per cent. were positive. Fifty-two cases in the first or second stage, but with intercurrent affections, gave 89·4 per cent. of positive results. In 12 cases of pleural effusion of tuberculous origin only 9 per cent. were positive, while in 15 cases of dry pleurisy as many as 86·6 per cent. were so. In 18 cases of tuberculous meningitis and in 10 cases of miliary tuberculosis the results were uniformly negative. In 75 cases of tuberculosis in regions other than the lungs the positive results were as high as 96 per cent. Of patients clinically non-tuberculous, 121 were examined with only 17·3 per cent. positive, while 62 healthy persons only showed 3·2 per cent. of positive results. The number of positive Wassermann reactions obtained was 24 per cent. among the tuberculous patients and 35·5 per cent. among the others. If the Wassermann reaction is strongly positive and the clinical examination is doubtful, the result as regards the tuberculous reaction must be taken with reserve. It is interesting to note that in advanced pulmonary tuberculosis the reaction may be absent or only partial, that it is very often negative in pleural effusion, and almost invariably so in miliary tuberculosis and tuberculous meningitis. The authors are of opinion that their serum reaction is of definite clinical value, and their results if confirmed by other observers on a large scale would seem to justify their claim.

Revista de la Sociedad Medica Argentina.—This review for November and December, 1914, which has only just reached us, comprises some 400 odd pages, and those responsible for its production may be congratulated on the interest of its contents, the excellence, alike from the scientific and from the technical point of view, of its illustrations, and the quite noticeable beauty of its typography, the latter a feature which has struck us in other periodicals from Spanish and Portuguese America. The present volume opens with an article on the topography of the sphenoidal sinus by Dr. Ricardo Laspius, which contains much to interest both anatomists and pathologists, and is enriched by a number of admirable photographic illustrations.—Dr. Udaondo and Dr. Castex write on the myelodysplasia of Fuchs, citing three illustrative cases of this malady, the main characteristic symptoms of which are nocturnal enuresis, a general infantilism, certain skeletal malformations, hypertrichosis, and a marked degree of webbing between the second and third toes.—Dr. Ragusin recounts four interesting cases of twin birth in which, while one twin exhibited marked signs of congenital syphilis, the other was perfectly healthy.—Dr. Viñas describes an operative procedure—invagination of the appendix—which he advocates as an operation of election in all cases of early interference in which advanced lesions of the appendix and adhesions are absent. The appendix, after ligation and division of its mesentery, is invaginated into itself like the finger of a glove, the invagination being continued until the organ has completely disappeared into the cæcum, the little pucker left at the site of the base of the appendix being closed by a few peritoneal sutures. The invaginated organ, deprived of blood-supply, necroses and sloughs off into the cavity of the cæcum and passes per anum some five or six days after the operation. The author recommends this operation as easy, rapid, and, owing to the avoidance of any opening of the appendix, aseptic.—Among other articles of interest special mention may be made of that by Dr. Gonzalez on gravido-dynamic deformities of the pelvis, in which he maintains the erroneousness of the generally accepted view that dystocia from pelvic deformity is impossible in a woman to whom normal parturition has occurred, unless osteomalacia be present—in other words, that pelvic deformity, other than osteomalacia, is always primitive, independent of the gravid state and antecedent to the first parturition. Dr. Gonzalez maintains, on the contrary, that the gravid state may itself be a determining cause of pelvic deformity, and that the shape of the pelvis may alter between one parturition and the next, quite apart from osteomalacia. The article is copiously illustrated by outline figures of museum specimens and is an able and scholarly presentation of an interesting thesis.

In the *Revista Medica del Uruguay* for March Dr. Luis Morquio contributes a valuable article on the Diagnosis of Appendicitis in the Child.

Malaria e Malattie dei Paesi Caldi. Anno VI., April 20th, 1915. Rome: Via Farini 62.—This issue contains a report of a case of beri-beri by Dr. Lacava. The case was a typical one, and is of interest from the fact that it occurred sporadically in a village of Calabria in a girl who had never left her native country but who habitually ate large quantities of rice, sometimes to the exclusion of all other diet.—Dr. G. de Angelis, continuing his investigations on the streptobacillus pellagræ, which is considered by Professor Tizzoni to be the cause of that disease, has been able to demonstrate the presence of the organism in the stools of patients suffering from it. The identity of the organism in the stools with that obtained from the blood was proved by morphological characters and pathogenic culture; but while in the blood it assumes variations of form in relation to different phases of the disease, in the stools it always presented a more definite and fixed form.—Dr. F. Giugni has a paper on the transmissibility of canine leishmaniasis. Two puppies which lived for two months with a bitch affected severely with spontaneous leishmaniasis, and subsequently dying of it, were quite unaffected by it, although every measure was taken to favour the transmission of infection by fleas. Another paper on this disease is by the same author on the behaviour *in vitro* of Leishman bodies in the presence of other micro-organisms.—Sprue in Calabria and Sicily is the subject of a clinical contribution by Professor N. Gabbi, in which he describes several cases in a lucid and interesting manner. He inclines to the germ theory as the cause of this disease, and considers it probable that the infection is imported from the East by vessels which arrive at the port of Messina.

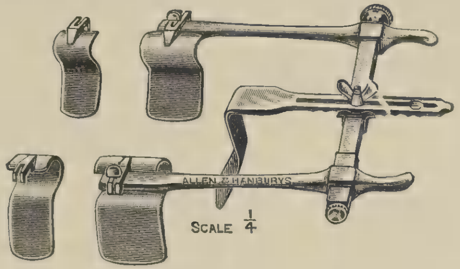
AT the Senate House, Cambridge, the Rede lecture has been delivered by Dr. Norman Moore, who took as his subject St. Bartholomew's Hospital in Peace and War.

Dr. and Mrs. A. C. Jordan are giving a concert on Saturday, May 29th, at 4.30 P.M., at 13, Upper Wimpole-street, in aid of the "Music in War-time" Fund. The tickets, 5*s.* each, will include tea, and payments received in excess of the price of tickets will go to sufferers from the loss of the *Lusitania*. The artists include Madame Amina Goodwin, Miss Cecilia Gates, Miss Adelina Leon, and Mr. Edward Halland.

New Inventions.

A SELF-RETAINING BLADDER RETRACTOR.

THE efficient exposure of the interior of the bladder is the key-note to modern operations on that viscus. Some years ago I introduced a bladder retractor ("Genito-Urinary Surgery," Messrs. Cassell and Co.) with an easily grasped handle which gave a maximum exposure of the interior of the bladder for the size of the abdominal incision. In order to diminish the amount of assistance required at operations on bladder growths I have had the blades of the bladder retractor fitted on an abdominal frame so that they can be slipped into the cavity of the bladder, separated, and remain in place, retract the abdominal wall, and hold the lateral walls of the bladder well apart. The blades are detachable; so that a small or large size blade may be used, as the exigencies of the operation demand. A third blade is attached by means of a screw to the transverse base of the frame. It is movable in an antero-posterior direction and serves to push back the posterior wall of the bladder.



The instrument, which is shown in the illustration, is made by Messrs. Allen and Hanburys, Limited, Wigmore-street, London, W. It has been in use for two years, and has been proved to be highly efficient.

J. W. THOMSON WALKER, F.R.C.S. Eng.

Queen Anne-street, W.

(1) ELECTRICAL STERILISER; AND (2) ELECTRICAL COOKING APPARATUS.

THE utilisation of electric energy for general heating purposes is rapidly being brought into line with economic considerations. The principle, of course, was established long ago, but the problem has been to render the system available for practical purposes at a cost consistent with that entailed by existing methods. A very important advance in this direction has been made by the resistance system introduced by Mr. R. F. Venner, of the Venner Electrical Cooking and Heating Appliances Co., Ltd., of Venelectric Works, Wandsworth-road, London, S.W. In using what may be called naked resistances, which amount to coils of red-hot wire, there is an obvious loss of heat in many ways. One requirement is to insulate the resistances effectively against loss by radiation and at the same time to secure their heat for the given purpose. Further, it is desirable not only to utilise this heat, but to distribute it uniformly. Mr. Venner effects this by immersing the resistance coils in a specially prepared heavy petroleum oil. It is as though the filament of an ordinary electric incandescent lamp were submerged in oil, which would prevent its getting red-hot, but at the same time the oil would reach a temperature sufficiently high for cooking or other purposes. The oil must be capable of resisting carbonisation or charring, a negative quality which is obtained by selecting an oil that has received a special preparatory process. It only remains, therefore, to construct a suitable container jacketed with this oil in which the resistance coils are immersed. This container can take the form of a sterilising tank, a grilling pan, a kettle, a roasting chamber, and so forth. The thermal efficiency of the steriliser has been certified to be 82·6 per cent., while the value of the resistance shows no impairment even after running continuously for 100 hours. In hospital practice this steriliser is of the greatest convenience.

We have made a personal trial of the silver grill and the results are very satisfactory. The heating efficiency is reached in two and a half minutes and then a chop, steak, egg, or slice of ham can readily be cooked in a surprisingly short time. The cooking is effectively done, the contact with the hot plate causing coagulation of the albumins so that the juices are retained, with the result that meats are tender and appetising. It makes omelettes perfectly, and a sole fried by this method is most attractively cooked. In one experiment 3 lb. of steak were cooked in 9½ minutes, the current taken being 71·25 watts, which at the rate of 4½*d.* per unit costs about ⅓*d.*; in another experiment 2½ lb. of kidney and mushrooms were grilled in 6½ minutes with a consumption of 54·16 watts, the cost of which, on the same basis of charge, would be less than ¼*d.* The introduction of this method marks a considerable advance in the application of electricity to cooking purposes on the score of both economy and efficiency. The grill can be used in any room of the house in which there is an electric lamp, obviously a convenience in a time of sickness or emergency.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION:

Summary of Reports for Month ending Feb. 28th, 1915.

Clark, B.Sc., Leith, Stirling, and Paisley respectively. The correspondents referred to in col. 2 are for the most part public health authorities.

THE LANCET.

LONDON: SATURDAY, MAY 22, 1915.

The Report of Lord Bryce's Committee.

The committee appointed by the Government in December to examine into the charges of outrage and cruelty which had been made against the soldiers of Germany from the very first days of the war made its report last week too late for notice in our columns.[1] The medical interest of the document is very great in several directions, while the composition of the committee gives particular force to its conclusions, for it was exceptionally fitted to discharge its task. No political element could afford any ground for the suggestion of bias in one direction or another. The name of its chairman, Lord Bryce, was known and honoured throughout the world, in enemy countries as well as in those of neutrals and at home. The four King's Counsel among its members comprised men of such divergent aims and attainments as Sir Frederick Pollock and Sir Edward Clarke, and the inclusion of Mr. H. A. L. Fisher and Mr. Harold Cox showed that the necessity for judging present acts by the light of history had not been forgotten. The report of such a body will carry weight now and hereafter, and will be closely studied not only in the countries at war but in those which have remained interested and critical spectators of the struggle. And its particular value is that its revelations, appalling as they are, will serve to steady our emotions at a moment when national feeling is at fever heat and when exaggeration is apt to colour stories which pass from mouth to mouth, and when invention with but a slender foundation of fact often obtains currency more readily than plain truth. There have been exaggerations and flat lies in connexion with the war, and rumours upon many subjects have been proved false or have died for lack of corroboration. (We might cite the stories of Russian reinforcements from Archangel as an instance of what rumour can achieve when once a story is set in motion.) And in the matter of German outrages there have been misstatements. There are not in this country, as was at one time declared, thousands of young Belgian girls expecting to become mothers as the result of rape by the soldiers of the enemy, any more than there are thousands of English girls pregnant as the result of our own soldiers' licentiousness. But the sifting of the evidence with regard to German atrocities has produced a record of villainy which will reduce to their proper value the vapourings of those who regarded all stories of inhumanity in the foe as idle libels. The world now knows a good deal of the truth.

Such a report as that issued by Lord Bryce's committee dispels rumour and exaggeration, substituting facts horrifying enough in themselves to require no admixture of fiction to render them more terrible. Murder, rape, and robbery have been committed throughout the areas invaded by the enemy, and these crimes have not been sporadic manifestations of the awakening of brute passions in undisciplined soldiery inflamed by war and conquest, but have been in many instances the result of deliberately sanctioned terrorism, planned with a view to subjugating the countries attacked and those defending them. These crimes have been committed by the most rigorously and meticulously disciplined army that the world has ever seen, and their cruelty has been carried to an excess which the world has not felt since it has boasted itself civilised. This is the gravest part of the charge now proved against our enemy; that those in high authority inculcated the practice of barbarous outrages in soldiers whom they provided with ingeniously devised contrivances for spreading fire in buildings, as they have since armed them with even more ingenious equipment for carrying and releasing poisonous gases. This portion of the damning charge is proved beyond any room for doubt, not only by witnesses deposing to the speeches of German officers who justified their acts by alleging the orders of their superiors, but by documentary evidence of various kinds of unquestionable authenticity, convicting the accused by their own confession. It is not necessary to give extracts here from the evidence. The document has been read by many, and will shortly be familiar to all, as the Government proposes to issue it publicly at a nominal price. But we wish to insist on the manner in which the evidence has been collected and sifted by the committee, in order to show that nothing has been allowed to pass which could be characterised as dubious or incapable of proof. The committee itself admits in its report, which is unanimous on all points, that it "began the inquiry with doubts whether a positive result would be attained. But the further we went and the more evidence we examined so much the more was our scepticism reduced." In another passage dealing with this topic we are told: "The force of the evidence is cumulative. Its worth can be estimated only by perusing the testimony as a whole. The experienced lawyers who took the depositions tell us that they passed from the same stage of doubt into the same stage of conviction." That "shadow of reasonable doubt" with which we are familiar in our courts of criminal jurisdiction finds no place when we study the broad outlines of the report. Assassination, lust, and pillage have prevailed over many parts of Belgium on a scale unparalleled in any war between civilised nations, and no military necessity can be alleged in defence or extenuation of the outrages thus committed.

---

[1] Alleged German Outrages: Report of Committee. 3d. Appendix, 2s. 1d. London: Messrs. Eyre and Spottiswoode, Limited; Messrs. Wyman and Sons.

There is one breach of those rules of civilised warfare that are sanctified by usage and rendered definite by signed convention to which special reference may appropriately be made in these columns. The committee found a difficulty, inherent to the circumstances of the act, in establishing the intention of firing upon hospitals, ambulances, and stretcherbearers, where the firing was conducted at long ranges. It therefore declines to declare that there is proof of this crime, merely pointing out that military observers believe that it took place, and that in the case of ambulances explicit evidence exists. Abuse of the Red Cross by the enemy was, however, found capable of more direct establishment. This abuse, according to witnesses, consisted of the opening of fire sometimes at close range with machine guns disguised in ambulances, and a case is described in which there is little room to doubt that a Red Cross motor-car was used to carry ammunition under the command of officers. It is observed that "unless all these statements are wilfully false, which the committee sees no reason to believe, these acts must have been deliberate, and it does not seem possible that a Red Cross car could be equipped with a machine gun by soldiers acting without orders." From the closing remark of this passage none will dissent who remembers that the German army conducts its operations under the strictest discipline applied to the minutest details. The abuse of the Red Cross is a crime of warfare the stain of which will never be effaced.

Deep and burning indignation will be aroused in those who read the story told in dispassionate language by the committee. The acts recounted have inflamed the anger of those actually engaged in fighting to a degree of bitterness of which they would once have believed themselves incapable. These, however, in many cases have been eyewitnesses of that which they are not likely to forget, and they have the perpetrators before them. For us at home there remains the duty to possess our souls in patience and to contribute in every way in our power to the bringing of the war to that conclusion which will ensure the meting out of justice to the wrongdoers and the establishment of lasting peace. We shall in no way aid in the attainment of that end by indulging in frothy ebullitions of rage, in rousing the passion for mischief in persons naturally unruly and excitable, or in calling for "reprisals" against those who have neither done nor ordered the acts which are the cause of our anger. We can express no sympathy with those who recently have wrecked shops in London and elsewhere, and pursued aliens believed to be Germans in the streets. Deeds of this kind, carried out principally by women and boys, can have no effect upon the course of the war, and the men taking part in them would do better by exhibiting their fighting qualities, if they have any, in the ranks of the army. On the desirability of interning Germans or of preventing by law the carrying on of their businesses we offer no opinion. It is outside the province of THE LANCET to do so. Rioting against them is a different matter, and we protest against public exhibitions of excitement as mentally and morally demoralising to those indulging in them, and as likely to lose us the reputation for sober sense and steadfastness upon which as a nation we have long prided ourselves. It is by their enduring steadfastness that our soldiers have earned undying fame during months of trench warfare. It is for us to emulate them in their dogged determination, and to support them by every means in our power. Attention must not be diverted to anything that is irrelevant to the great matter that we have in hand. Riots, shouting, and displays of temper will help us not at all, nor will the discussion of plans for the punishment of those responsible for the crimes revealed in the report of Lord BRYCE'S Committee. Our aim and that of our Allies is to prevent the recurrence in the world's history of the horrors amidst which we now move.

◆

The Medical Research Committee and the War.

AN interim report has been issued on the special work in connexion with the war which is being undertaken by the National Health Insurance Medical Research Committee. The report is addressed to Mr. MONTAGU, chairman of the National Health Insurance Joint Committee, and gives a very interesting résumé of the special activities of the Research Committee which have had their outcome in the war, and which, it should be understood, have been additional to previously organised schemes of research. It was foretold that the value to the country of the Research Committee, with its regular income and strong scientific staff, would surely prove to be high; in wholly unlooked-for circumstances the surmise has proved to be correct.

There are two main directions in which the Medical Research Committee are labouring as a result of having placed their services at the disposal of the War Office, and both are sure to be of great utility to the country immediately and to pathologists and statisticians later. The committee are undertaking, first, the compilation and analysis of the medical statistics of the sick and wounded from the military forces; and, second, the assisting of the military hospitals in this country to carry on the pathological side of their work efficiently. The whole resources of the statistical department of the Committee are now available for the purposes of the war. The compilation of the statistics of our sick and wounded is under the direction of Dr. JOHN BROWNLEE, who, with Colonel H. P. W. BARROW, R.A.M.C., and Colonel W. N. BARRON, R.A.M.C., it may be remembered, has become responsible for the statistical section of the official medical history of the war. A proper statistical investigation dealing with the sick and wounded, even among the British soldiers only, in this gigantic struggle will furnish lessons for the future of the highest importance. The circumstances of the war have been and are in many respects unprecedented, and we may receive specially significant information from the statistical analysis of the casualty and sickness lists; apart from which our previous wars have been so badly chronicled from the medical point of view that much general instruction to be gathered from the figures will be new to us. Similarly the assistance which the Medical Research Committee have been able to offer to military hospitals in respect of their pathological departments has not only been of great practical service in the care of our sick and wounded, but is likely to have far-reaching results. In some of the places where medical officers, having commissions, have been appointed to pathological posts, the Medical Research Committee have made grants for the supply of apparatus such as would not necessarily be found in the ordinary equipment of a hospital; to other military hospitals grants have been made for the appointment of part-time pathologists, not having commissions, whose work can in some cases be carried out in an adjacent laboratory belonging to a university or a municipal authority. In some cases the Medical Research Committee have equipped laboratories within military hospitals for the purpose of routine work or special inquiry. The work here done in collaboration with the Royal Army Medical Corps, whose scientific status is now so good, and whose achievements throughout the war have been recognised as a feature in our military successes, is bound to throw light upon many difficult problems in preventive medicine and therapeutics.

Among the special inquiries which the Medical Research Committee are employed upon may be mentioned the study of epidemic cerebro-spinal meningitis, which is being undertaken under the direction of Dr. M. H. GORDON, who has received a commission as a major in the Royal Army Medical Corps, and who has a central laboratory at the Army Medical College, Millbank, where the Committee provide him with two assistants. Research in the same direction in many provincial laboratories is also being subsidised. The services of the bacteriological department of the Committee, which is under the direction of Sir ALMROTH WRIGHT, have been applied to purposes of military significance, while it is well known that at the outbreak of the war Sir ALMROTH WRIGHT and his staff gave the whole of their time to the preparation of vaccines for the army in the inoculation department of St. Mary's Hospital. We publish elsewhere in full the interim report of the Medical Research Committee, which tells its own story of multifarious industry, and feel sure that no medical man can read it without seeing how fitting an adjunct to the labours of the Royal Army Medical Corps the Committee are proving themselves to be.

Annotations.

"Ne quid nimis."

THE LATE MADAME DEPAGE.

IT is felt that the tragic death of Madame Depage, to which reference was made in our columns last week, should not be allowed to pass without some demonstration of the admiration that is felt for her character and of sorrow for her tragic fate while engaged on an errand of mercy. Madame Depage had many friends who were deeply attached to her both here and in the United States, and it is thought that they might like to give expression to their feelings by subscribing to a small bronze memorial to be placed in the Depage Hospital at Brussels after the war. The memorial might be executed by some of the distressed Belgian art metal-workers who are now in exile. Subscriptions will be gladly received by Mr. Robert Jones, 11, Nelson-street, Liverpool; by Mr. D'Arcy Power, 10A, Chandos-street, Cavendish-square, London; or by Professor Sinclair White, Ranmoor, Sheffield.

THE TREATMENT OF THE ATONIC WOUNDS OF WAR.

AT a recent meeting of the Société Médicale des Hôpitaux of Paris M. François Debat described a simple and effective method of treating the wounds of war which resist ordinary methods and remain atonic or even degenerate into ulcers. Our Paris correspondent has already referred briefly to the treatment as being satisfactory. The wounds in which it was employed were usually not deep. At first they showed nothing particular and then the following obstinate condition gradually developed. The wound became violaceous and its surface smooth or mammillated with soft granulations, the borders punched out or nodular. There was an abundant serous or purulent discharge. Sometimes a thin violaceous cicatrix formed at certain points with little power of resistance. In other cases the ulcer increased in depth and extent. This complication usually occurred in soldiers who were debilitated, fatigued, or addicted to alcohol, but sometimes was observed in young, robust, and sober men without specific or tuberculous history. Atonic wounds showed a predilection for certain situations—the backs of the hands and feet, the inner surface of the arm, and the antero-internal surface of varicose legs. They were never observed on the face or the plantar or palmar regions. Ordinary treatment was of no use. Antiseptics only irritated and destroyed the tissues. Moist dressings macerated the surrounding integument and provoked dermatitis and folliculitis. Dry dressings adhered to the wound and formed a crust under which suppuration spread downwards. In many cases, after two or three months' treatment, the condition was worse than ever. The localisation of the wounds gave the key to their pathogenesis. As stated, palmar and plantar wounds healed well. Three reasons may be given for this. 1. The thickness of the integuments, particularly of the generating Malpighian layer. 2. The activity of the circulation. 3. The frequency of contraction of the subjacent muscles. In the regions where the atonic wounds occur there are, on the contrary, a thin epidermis, a circulation of little activity, and feeble and infrequent muscular contractions, as the wounded man tends to immobilise the affected limb. The treatment follows. Irritation of tissues with little power of resistance must be avoided. Their activity must be increased by movements and massage. M. Debat eliminates all antiseptics. He applies a light dressing of gauze soaked in saline solution of the strength of 9 per 1000 covered with cotton wool. To prevent maceration he exposes the wound every day to the air and increases the duration of the exposure as the discharge diminishes. The time of exposure is two hours on the first day, and this is increased by an hour daily. When the discharge ceases the saline solution is replaced by a thick paste of oxide of zinc or innotyol. Every hour the muscles subjacent to the wound are moved for five minutes, while the limb is maintained in an elevated position. Every day effleurage of the limb with pinching of the skin around the wound is performed. If the wound is in the lower limb the patient should remain in bed; if in the upper limb he should wear a sling. This simple method had an immediate effect. The following is an example. On Oct. 28th, 1914, a robust soldier, aged 21 years, addicted to alcohol, sustained a superficial wound on the antero-internal surface of the arm in consequence of a shell explosion. The wound was painted with iodine and moist dressings were applied. After a fortnight the wound suppurated abundantly and tended to enlarge. Peroxide of hydrogen, nitrate of silver, iodine, permanganate of potassium, carron oil, and dry dressings were tried in turn. After two months there was no improvement. On Jan. 8th, 1915, the treatment described above was adopted. The movements consisted in pronation, supination, shutting the hand, and flexion of the forearm. After three days the wound was red instead of violaceous, and was granulating, particularly at the borders and lower end. On Jan. 26th healing was complete.

HOW PLAGUE MAY BE CARRIED FROM PLACE TO PLACE.

IT is now generally recognised that plague may be conveyed from port to port or from one continent to another by infected rats which may travel on board vessels, concealed like stowaways among the cargo. Modern preventive measures, therefore, require a careful examination of sacks, crates, boxes, or other packages before they are carried on board ships at the port of departure and again before landing at the place of destination to discover if any rats are concealed in them. Our American contemporary, *Public Health Reports* of March 26th, calls attention to what appears to be an illustrative example of this possible danger. Recently at Seattle, a seaport town situated on Puget Sound, in the State of Washington, on the Pacific coast, a large box of plants arrived from Japan, and on being opened by the State horticulturist a rat was discovered concealed in the soil at the bottom of the box. The animal was at once killed with a stick and the body was handed over to the medical officer of the Public Health Service stationed at Seattle for examination, with the result that it was found to have been suffering from a form of plague. There were two possibilities —namely, that either the rat had entered the box at Yokohama before it was carried on board the ship, or that it had managed to enter the package at Seattle when it was opened by the official appraiser for customs purposes. The experts who inquired into the case came to the conclusion that the affected rat must have entered the box at Yokohama and travelled in it to Seattle. For some time the local rats at Yokohama are known to have been infected by plague, but on the other hand it is equally true that since 1913 plague-infected rats have been found from time to time at Seattle up to the beginning of the present year along the water front. After consideration of the facts we are disposed to agree with the view taken by the Seattle experts that the infected rat was conveyed from Yokohama in the box of plants, and that it was extremely unlikely that it could have managed to find its way into the package during the short examination made by the official appraiser at Seattle. If this view be correct the importance of the case can hardly be over-estimated, for if the box had been consigned to some inland town in the United States where the public health officials were not on the alert, it is more than probable that the infected rat would have escaped to mingle with the local rats, and might have established a fresh focus of plague infection. We understand that the medical officers of the United States Public Health Service have now instituted a systematic examination of all packages coming from infected ports in order to ascertain the relative frequency of such occurrences, so that suitable steps may be taken at Seattle and other ports to prevent any danger that might arise from this cause in future.

THE ASSAY AND PHYSIOLOGICAL VALUE OF MEAT EXTRACTS.

AN interesting discussion on the methods adopted in the estimation of the nitrogenous constituents of extracts derived from albuminous substances, such as meat extracts and similar products, with special reference to the physiological significance of the results, was opened by the chairman, Mr. A. C. Chapman, at a joint meeting of the Society of Public Analysts and other Analytical Chemists and the Bio-chemical Society, held at the Chemical Society's rooms on May 5th. The chairman drew a sketch of the analytical methods in vogue which aimed at separating and estimating such products as gelatine, gelatin-peptone, syntonin, albumoses and peptones, creatin and other meat bases. Dr. F. Gowland Hopkins, in the course of some interesting remarks on the work that was being done on the subject at Cambridge, said—

> The animal body dealt not with the intact proteins or even with the albumoses and peptones, but with the free amino-acids which were the individual constituents of the protein molecule. The actual way in which the different amino-acids were grouped in the protein molecule was not of much consequence, but the effects produced by the individual amino-acids were of extreme importance. He described physiological experiments which he had made showing that when rats were given a diet including a complete amino-acid mixture corresponding to the proteins of an ordinary diet the growth was almost exactly normal, while when arginine and histidine were removed from the amino-acid mixture the growth ceased immediately, being resumed when arginine and histidine were again added. The removal of tryptophane from the amino-acid mixture also produced similar results, and Osborn and Mendel in America had shown cystine to be similarly essential. It did not follow that this was the case with every amino-acid, and the question as to which of the amino-acids were essential in that way offered a large field for investigation. Recent work at Cambridge indicated that certain acids could be removed from the amino-acid mixture without affecting the

rate of growth. With regard to the minimum quantity of any amino-acid required for nutrition, experiment had shown that, in the case of rats, at any rate, the critical minimum for arginine lay somewhere between 2½ and 1 per cent.

It appeared that the functions of the individual amino-acids were not confined merely to flesh formation. The effect of feeding animals on zein, which was deficient in both tryptophane and lysine, was not only to restrict growth but also to shorten the survival, and the same was observed with zein plus lysine; but with zein plus tryptophane the animal was able to maintain its weight for a long period, although it did not grow. It was clear from this that trytophane exercised some other function than the mere supply of material for growth.

Mr. A. R. Tankard thought that it was important in some cases to estimate separately the meat fibre and coagulable albuminoids, with a view to the detection of extraneous matters which were sometimes added. For some time past he had adopted the method of centrifugalising the bromine protein precipitate, mixing the residue with water, and centrifugalising again. He made a practice of separating the albumoses and peptones, but agreed that in most ordinary cases this was of little value. There were, however, on the market certain so-called "fortified" meat extracts which contained albumoses and peptones in very much larger proportion than occurred in ordinary meat extracts.

Dr. Percival Hartley described his experience of Van Slyk's method of determining amino-nitrogen, which was based on the fact that when protein and protein degradation products were treated with nitrous acid nitrogen gas was given off. The results of complete analysis of various proteins showed that the constitution of serum albumin was quite different to that of the globulins, the former containing a much larger proportion of lysine and of cystine than the latter. Another interesting result was that the globulins exhibited no difference in chemical composition—eu-globulin and pseudo-globulin apparently being closely related. Another point brought out was that the free amino nitrogen of native proteins appeared to be approximately one-half of the lysine content which, if substantiated, would appear to afford a simple method of estimating lysine without hydrolysis of the protein. Furthermore, the proportion of free amino nitrogen indicated to what extent the protein had been digested or peptonised.

On the whole the discussion did not throw much fresh light upon the actual value of meat extracts as nutrients. The general impression was derived that there might be activators present in such extracts which were of value in encouraging the assimilation of actual food substances, and so the classical conclusion that meat extracts served as adjuvants or stimulants rather than direct nutritives would appear still to hold the field.

THE REGISTRATION OF PLUMBERS.

THE protracted efforts of the Worshipful Company of Plumbers, no less on behalf of the public health than for the honour of the trade they represent, are slowly bearing fruit. Recently the corporation waterworks of the county borough of St. Helens issued a regulation to the effect that for the protection of the water-supply, and in the interests of the consumers, it is essential that all plumbing work should be well and soundly executed; and in order to ensure the employment of none but good workmen a register of plumbers will be kept in the office of the water department of the corporation, on which may be enrolled any plumber carrying on business within the limits of the water-supply who shall satisfy the water committee and the engineer in all respects as to his competency, and who shall sign an agreement to conform to and comply with the by-laws relating to water-supply. No other person will be recognised as an authorised employee. Still more recently, on April 24th, the annual general meeting of the Incorporated Joint Committee on Water Regulations was held at the London Guildhall, at which was passed a resolution approving the principle of "raising the qualification of plumbers employed on water fittings, and calling on water authorities to recognise and require as far as possible the employment of plumbers qualified and responsible for the efficiency of their work by having passed a theoretical and practical examination, such as that conducted by the General Council for the National Registration of Plumbers, which is constituted of representatives of master plumbers, operative plumbers, and authorities connected with public health." It was further recommended that where there was not a sufficient supply of plumbers possessing the necessary qualification the water authorities should obtain information from the plumbers of the locality as to the reason for the apparent insufficiency and the possibility of increasing the number of properly qualified men. It is hoped that regulations such as the above will influence all plumbers to bestir themselves with a view to obtaining some certificate as to their competency. Hitherto the majority of plumbers, we regret to say, have abstained from registration, finding themselves able to obtain employment without payment of the annual 5s. fee necessary for registration. While this narrow attitude continues the public are left without any guarantee of the workman's ability to execute properly the work which he undertakes, and bad results to the public health follow.

THE PHYSIOLOGICAL SIGNIFICANCE OF REFLEX PHENOMENA IN SPASTIC PARALYSIS OF THE LOWER LIMBS.

THE elaborate observations reported by Dr. R. Walshe in *Brain* (1914, Vol. XXXVII., p. 269) is of much more than passing interest. They are of high clinical and diagnostic importance; they instance, too, a striking example of the value to clinical medicine which apparently purely physiological data can afford. Professor C. S. Sherrington's researches upon the "spinal" and the "decerebrate" animal form the starting-point. It has been shown by him that there are two separable systems of motor innervation which control two sets of musculature. One system exhibits those transient phases of heightened reaction which constitute reflex movements, well exemplified in the protective reflex of flexion following a nocuous stimulus to the sole of the foot; the other maintains that steady tonic response which supplies the muscular tension necessary to attitude, and which is mainly evidenced in the extensor group of muscles. These two systems, moreover, coöperate, exerting influences complemental to each other. Does this system of innervation apply in man? Dr. Walshe brings forward what appears to us to be convincing evidence that it does. He recognises, with Babinski, two forms of spastic paraplegia: one "in flexion" when the limb or limbs become flexed, and the other "in extension" with the limb extended. In paraplegia with flexion one has muscular rigidity in flexion, profound loss of voluntary power, diminished or absent tendon-jerks, and exaggeration of the defence reflexes and extensor response (the Babinski sign, which Dr. Walshe argues is a definite part of the flexion reflex). Such a form of paraplegia is met with especially when there is local and extensive cord damage, when, it is suggested, not only the pyramidal tract but the lateral columns also are affected. In a pure pyramidal lesion, such, for example, as hemiplegia, there is, on the contrary, always paraplegia in extension, not in flexion. Now, flexion paraplegia, on account of the loss of knee-jerk, which represents the degree of extensor tonus, indicates interruption of those motor channels concerning such tonus, and since this interruption never occurs in pure pyramidal lesions it is argued that such channels pursue an extra-pyramidal course. Flexion paraplegia in fact corresponds to Sherrington's "spinal" animal, in which the cord is definitely interrupted. Extension paraplegia presents a different condition. There is here the exaggerated knee-jerk; there is, that is to say, evidence of heightened extensor tonus, and such a condition corresponds to Sherrington's decerebrate rigidity. Now, the same condition follows, experimentally, section of the brain-stem above the level of the pons, but not so far forwards as the forebrain. The centre controlling this extensor reflex lies probably near the paracerebellar nuclei. In animals, therefore, it is suggested that of the two reflex centres controlling flexor responses and extension tonus respectively that subserving flexion rests in the cord, and that preserving tonus in the extensors rests in the brain at the site suggested. A pure spinal lesion generally causes flexion paraplegia, for here the tracts for extensor tonus are usually involved as well as the flexion "spinal" centre. A cortical lesion, such as hemiplegia, representing a pure pyramidal lesion, always causes extension paraplegia, for here the paths for extensor tonus are not interfered with; the tonus is, indeed, heightened. This increased tonus may modify the character of the reflexes of its antagonistic muscles, the flexors, where the crossed extensor response is only obtained in such conditions. Disturbance of sensation appears to influence hardly appreciably the form of these reflexes. The investigations have been followed in some cases by means of graphic records of the tendon-jerks. The analogy between events as seen in the experimental animal and those furnished by pathological conditions in man is thus of striking significance, and the power of diagnosis is materially aided by this "lift up" from the physiological laboratory.

INSANITY CLAIMED TO BE DUE TO MINERS' NYSTAGMUS.

THE causation of insanity is a wide subject, which it would be impracticable to endeavour to reduce to fixed or specific limits by the definite inclusion of certain factors and the rigid exclusion of others. At the same time, if attention is devoted to what may appear the most prominent incident in the previous history of a case, and a proportioned estimate of the action of less obvious but at least equally potent factors is not made, there is grave risk of misconception and of erroneous judgment. Nothing is more clear in discussing the incidence of insanity than the fact that the soil from which mental disease springs is prepared by the inheritance of the individual, and the task of assigning relative importance to the various elements that must be regarded in any particular case of insanity is one demanding careful and mature consideration. In a recent case under the Workmen's Compensation Act nystagmus was claimed to be the cause of the insanity of the individual whose case was under adjudication. The Navigation Coal Company was sued by the widow of Walter Jones, a coal miner, for compensation in respect of the death of her husband as being due to nystagmus contracted when in the company's employment. The facts are briefly as follows. The deceased contracted miners' nystagmus and received compensation for a time. He subsequently took the position of steward to the Merthyr Vale Hibernian Club, and performed his duties to the satisfaction of the club. Later, however, he became obsessed with the idea that he was not doing his work satisfactorily, and he resigned. The club persuaded him to withdraw his resignation, but he resigned again, and this time his resignation was accepted. Before his notice expired he committed suicide on the railway, the coroner's jury returning a verdict of "Temporary insanity." In order to establish her claim for compensation the widow had to show that her husband's death was caused by nystagmus, which it will be remembered, is a disease included in Schedule III. of the Act of 1906. Evidence was called to establish the claim that his depression and suicide were the consequences of the disease which he had contracted. Judge Bryn Roberts, however, regarded the chain of causation as insufficiently demonstrated, and the widow's application was refused. Time and custom have sanctioned the division of etiological factors into "predisposing" and "exciting," and no physician will emphasise one at the expense of the other, for the operation of each is of significance. Of the predisposing factors in the case under consideration no information seems to be forthcoming, but assuredly they cannot be ignored, and whether predisposing factors are matters for compensation is too debatable a subject to be decided by mere *ex cathedrâ* statements. On the other hand, it can be understood that, where the soil is already prepared, the existence of such a physical defect as miners' nystagmus might become a veritable obsession in a particular case, and originate a train of morbid mental processes which might end in the commission of suicide. In a sense, therefore, it can be regarded as an exciting cause. Whether it was the only exciting cause in the present case is quite another matter, and, as already remarked, the part played by predisposing factors may be of equal, if not greater, importance. To assign compensation by singling out one only of a number of pre-existing morbid agencies at the expense of the others would be unjustifiable from the medical point of view, and equally unwise. The judge's decision that the chain of causation in this particular case was incomplete is one which we think expert opinion in regard to the causation of insanity will uphold.

THE VALUE OF ATOPHAN IN GOUT.

SOME observations on the use of this drug, which is a diphenyl-chinolin-tetracarbonic acid, have been recently published by Dr. P. Biffis in *Il Policlinico*. He administered it to five healthy and two gouty subjects in half-gramme doses two to eight times daily, the latter being on a rigorous purin-free diet. In the healthy subjects there was a definite increase in the uric acid eliminated by the urine, which generally reached its maximum in the first six hours, after which it diminished even though the dose was trebled or quadrupled. The increase was not in proportion to the amount of drug given after the first day, even if the experiment were made in the same individual at different times, and when the administration was suspended there was a diminution, sometimes very marked, in the quantity of eliminated uric acid which continued for two to three days. There was no change in the quantity of urine passed, but it became slightly turbid and high coloured and gave a sediment of urates and uric acid, and a trace of albumin was frequently observed. In large doses it was not well tolerated, causing pyrosis, which was not relieved even by full doses of bicarbonate of soda; this digestive disturbance was not nearly so frequent when novatophan was substituted for atophan. In the two gouty cases the drug was not given in the acute stages, and, taken in conjunction with other observations previously made by him, the author came to the conclusion that the drug was much less active with regard to the elimination of uric acid in gouty subjects than in healthy. It had hardly any action in doses of 1–2 grammes, and this may be why some observers have reported unfavourably of the drug. The inertia can perhaps be explained by the fact that atophan acts rather upon the elimination of exogenous uric acid and is therefore less active in gouty subjects on a diet free from uricogenous substances. With regard to the quantity of urine, the tolerance, and the albuminuria, the same phenomena were observed as in the healthy subjects. The action of atophan is little understood, but it probably consists in the decomposition of a larger quantity of nucleoproteids or in some alteration in those fermentative processes which regulate the oxidation of the purin bases.

PAINLESS LABOUR.

IN a recent issue of *La Clinica Ostetrica* Dr. E. Curti gives his experiences of 25 cases of labour in which he used a modification of scopolamine narcosis. Instead of the morphine with which this drug is usually associated and which has been blamed for some of the untoward results following its use, he had the idea of combining it with narcophine, a substance which is a synthetic double salt of morphine and narcotine having the chemical formula $C_7H_4O_7$, $C_{17}H_{19}NO_3$, $C_{22}H_{23}NO_7 + 4H_2O$. This substance is a white powder, soluble in water, and possesses the narcotic efficacy of opium without its toxicity. Its action is slower but more lasting than that of morphine, while its use is not followed by nausea. The technique employed by Dr. Curti was to give half-hourly injections commencing with scopolamine gm. 0·00045 (about 1/150th grain), with narcophine gm. 0·03 (about ½ grain). The second dose consists of scopolamine 1/200th grain alone, the third of the same quantity with the above dose of narcophine, the fourth of scopolamine alone, and so on alternately. The first injection was given as soon as the cervix was nearly fully dilated. Dr. Curti never found that the injections were followed by either nausea or vomiting, headache or giddiness. The patients felt well and were not fatigued, neither were there any hæmorrhages or other complications in either mother or child. The narcosis obtained is not complete, the mental faculties not being suppressed, but sensation is blunted and it is possible to administer food and medicine. Labour was never retarded and instrumental delivery, when it occurred, would have been necessary even without this narcosis, which is a great boon to a practitioner when single-handed. The duration of the narcosis after delivery varied, and depended partly on the number of injections and partly on the amount of blood lost during labour. Replying to the query whether the narcosis is due to the scopolamine or the narcophine, Dr. Curti's experience is that narcophine alone causes drowsiness but that large doses are required to overcome the labour pains, and with such doses probably uterine contractions would be diminished in intensity. The combination, however, with scopolamine enables smaller doses of narcophine to be used and produces sleep of short duration, together with almost complete cessation of the pain and abolition of full consciousness of what is taking place.

HOSPITALS AND RATES.

THERE is no encouragement to hospital governors to enlarge or even modernise their institutions if the case of the Royal West Sussex Hospital at Chichester can be taken as a test. Although no extra accommodation has been provided in bringing the institution thoroughly up to date, the local assessment committee has so increased the ratable value that the governors are called upon to pay annually on account of rates £80 more than hitherto. There may be strong arguments in favour of the increased assessment, but it seems unreasonable treatment of an institution which is doing thoroughly good work among the sick poor and has readily opened its doors for the reception and treatment of our wounded soldiers. The greater the work of the hospitals generally the less should be the taxes upon them: this would seem to be the more equitable way of regarding the position. Their whole purpose and tendency is to save expense to the community, and what is perhaps more important to improve the race. A very strong point against the increased assessment is that comparing the accounts of the institution at the Sussex cathedral city with hospitals in other comparable towns in no case is it found that such a heavy sum is being paid in rates in proportion to the number of beds. For example, the Royal Sussex County Hospital at Brighton, with nearly 200 beds, is assessed at only £104; the Royal West Sussex Hospital at Chichester, with 60 beds, £280; while the Portsmouth Hospital is not assessed at all, but *receives* £250 annually from the corporation. Further, two-thirds of the income of the Chichester institution are subscribed by those living outside the city borders; of an annual expenditure of £4661, no less than £3496 are spent in the city itself; and of the £16,000 raised to pay for the reconstruction the city subscribed £325, which sum included the bishop's subscription of £100. The complaint of the governors can well be understood, and in the event of relief not being granted there seem to be ample grounds upon which a friendly action might be cited.

THE next session of the General Medical Council will begin on Tuesday, June 1st, when the President, Sir Donald MacAlister, will take the chair at 2 P.M.

THE library and offices of the Royal Society of Medicine will be closed for the Whitsuntide holidays from Saturday, May 22nd, to Tuesday, May 25th, both days inclusive.

MR. J. B. Lawford, we understand, will offer himself again as a candidate for the Council of the Royal College of Surgeons of England, by the desire of his colleagues, as a representative of ophthalmology.

THE *London Gazette* announces that the King has sanctioned the appointment of the King of the Belgians as an Honorary Knight of Justice and of the Queen of the Belgians as an Honorary Lady of Justice of the Order of St. John of Jerusalem in England, and also the promotion of Adeline Duchess of Bedford from a Lady of Grace to a Lady of Justice of the Order.

Lieutenant-Colonel Hugh Jones Roberts, T.D., of Llywenarth, Penygroes, Carnarvonshire, has been appointed a Deputy Lieutenant of the County of Carnarvon.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Military Medical Students' Strike at Lahore.

SOME time last year the military students of the Lahore Medical School complained that the uniform worn was unsuitable. This complaint was endorsed by the Principal, considered by the Military Department at Army Headquarters, and certain alterations sanctioned; but owing to the demands of the war the materials necessary to carry them out could not be supplied. The students were also dissatisfied about the rates of scholarship allowances in these times of scarcity. During the visit to the school of Sir Pardey Lukis, the Director-General of the Indian Medical Service, on Feb. 20th, the Principal drew his attention to this matter, and Sir Pardey Lukis gave the representation sympathetic consideration; but on Feb. 22nd the second, third, and fourth year military students decided at a meeting to appear in plain clothes instead of uniform at the classes, contrary to the standing orders. Next day a body of these students were seen by the Principal leaving the hostel in mufti for their classes. They were ordered to appear in uniform before him at 9 A.M., and on doing so were given extra drills for their breach of discipline. The students went back to their boarding house, absented themselves from the classes, and subsequently held a meeting, at which they decided to go on strike. A part of the duty of these military students was the care in hospital of the wounded sepoy patients from the front, and they were also responsible for the unloading of the batches of wounded sepoys as they arrived at the hospital, so that they left the wounded soldiers unattended to, and but for the college students and the civil students of the school, who volunteered for the extra duty, not only must these patients have remained entirely neglected, but it would have been impossible to receive any more. On Feb. 23rd the Principal called on the students for an explanation of their absence from classes. The students stood silent, and they were then asked to take their bedding and leave the hostel for the night. They were told that the matter had been reported to the Director-General of the Indian Medical Service, and that they must await his orders before returning to their classes. They themselves wired to the Director-General and were ordered by him to return to duty, and to submit their grievances through the proper channel. The numbers concerned up to this time were 75 out of 117 military students; the remainder of the 352 students in the school had taken no part in the strike. On Feb. 24th 28 out of the 33 first-year military students joined the strikers, making 103 in all. On Feb. 27th the students on strike were informed by the Principal that the names of all the military medical students who did not return to their classes before 12 noon on March 3rd would be struck off the school rolls, that their scholarships in hand would be forfeited, and that all bondholders would be asked to make good their sureties. Practically none of the students returned by March 3rd, and the orders mentioned above were all carried into effect. In the meantime the Director-General had asked Colonel C. J. Bamber, Inspector-General of Civil Hospitals, to conduct an inquiry into the causes of the strike. After consideration of Colonel Bamber's report the Director-General issued orders that the students must return to duty unconditionally and submit to whatever punishment the Principal might consider it his duty to recommend, otherwise the orders already issued by the Principal, directing the removal of their names from the school rolls for grave misconduct, must hold good and their sureties would be called upon to discharge their bonds and pay up the amounts due. In compliance with these orders 13 students applied for re-admission and were again taken into the military class. The remaining 90 remained out on strike. The Principal then asked permission from the Director-General, I.M.S., to readmit suitable students who might even then apply, and under the orders of the Director-General March 27th was fixed as the latest date for receiving such applications for readmission. As none of the remaining 90 students availed themselves of this further period of grace offered to them by the Director-General they have ceased to have much chance of gaining readmission to the Lahore Medical School. The students apparently contend that they have never been on strike, but have always been ready to return to duty if they were taken back unconditionally and a consideration of their grievances promised. These contentions indicate a fundamental ignorance of the proper relation between pupil and an instructor, and of the requirements of military discipline, to which these students are subject. What else but a strike is persistent refusal to attend classes and carry out allotted duties? So long as the idea persists that in case of a difference of opinion between a professor and his students it is the right of the student to indicate terms to his instructor, such regrettable incidents as this strike are bound to recur.

Town Planning and Sanitation in Bombay.

Professor Geddes, lecturing in connexion with the town-planning exhibition, discussed in some detail the report of the recent Bombay Development Commission. The housing of the people in Bombay, he said, merited the most urgent consideration of the city, and he pointed out the inadequacy of the present rate of progress in regard alike to the decrease of the death-rate and increase of the population. A strenuous and organised civil endeavour was the prime desideratum of the town planning of Bombay. He characterised the planning of *chawls* of the present common type as warehousing the people and not housing them, and insisted that it was not impossible to make a large provision of respectable homes with sufficient playgrounds and not yet exceeding two storeys. Professor Geddes addressed an interested audience, for the public health of Bombay is much discussed just now.

The Bombay Sanitary Institute, which has been established under the auspices of the Bombay Sanitary Association, was recently opened by Lady Willingdon, the wife of the Governor of Bombay, when Dr. J. A. Turner (the medical officer of health of Bombay and honorary secretary of the League) and Lord Willingdon spoke of the establishment of the institute as a step forward in the sanitary education of the city. The Governor congratulated the municipality on what had been done in recent years, and assured them that Government were anxious to assist in every way possible. He thought that owners of property and large employers of labour had great responsibilities, and nothing would give him more satisfaction than to be able to see at the end of his term of office that something really substantial and practical had been done for the poor dwellers in the slums of the city.

Appointments.

Captain F. H. M. Chapman, R.A.M.C., to hold civil medical charge of Rurki, in addition to his military duties, vice Major E. H. Condon, R.A.M.C. Major G. A. Jolly, I.M.S., officiating civil surgeon, Gonda, to hold visiting medical charge of the Bahraich district, with effect from Dec. 21st. Major T. Hunter, I.M.S., civil surgeon, from Muradabad to Naini Tal. Dr. H. A. Macleod, civil surgeon, from Fatehgarh to Muradabad. Lieutenant P. S. Mills, I.S.M.D., officiating civil surgeon, from Mainpuri to Fatehgarh.

April 20th.

BRISTOL AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol: Temporary Residential College.

THE University of Bristol, like most of the modern universities, has been anxiously concerned since its foundation with the question of residential accommodation for its students. Early in its history it received an important benefaction for the accommodation of women students in the shape of Clifton Hill House, to which the adjoining Callander House has since been added. The last 12 months has seen the purchase of the Imperial Hotel and of a large property on Richmond Hill, Clifton, for conversion into halls of residence for men and women training students. The possibility of founding also a residential college near the University for men students generally has engaged the attention of an influential committee, and some progress has been made. The University has taken two houses in Belgrave-road, next to St. Mary's Church, Tyndall's Park, for the purpose of a temporary college. These houses are being renovated and decorated, and will be opened in good time for next term. When the arrangements are complete the temporary college will start with accommodation for 29 students, five in single study bedrooms and 24 in double study bedrooms. It will include also a refectory, a common room, quarters for a warden, and housekeeper's and servants' rooms, as well as bathrooms and offices. There are good-sized gardens at the back of the two houses which may be converted into tennis courts. The new temporary college is situated in a good residential part of the city; it stands high, and is within a few minutes of the University buildings. It is expected that the alterations will be completed in a few weeks' time, when the building will be open for inspection by present and intending students and their parents. The terms for board and residence have not yet been determined, but they will be similar to those charged in the residential colleges of other provincial universities.

Captain Ernest William Hey Groves, R.A.M.C., B.Sc., M.S., M.D.Lond., F.R.C.S.Eng., surgeon to the Bristol General Hospital, has left for the front on his appointment as operating surgeon to the new No. 21 Mobile Base Hospital.

The Late Lieut. Henry Wyndham Goodden, R.A.M.C.

Much regret was felt in Bristol at the news of the death of Lieutenant H. W. Goodden, who has recently been killed in action near Ypres. The deceased was the elder son of Mr. W. C. Goodden, who formerly practised for many years as a surgeon in Bristol. He was educated at Clifton College, and received his medical education at Bristol; he also studied at Paris and Vienna. He graduated M.B. and Ch.B. of Bristol in 1912, and the same year obtained the L.R.C.P. and M.R.C.S. qualifications. Before the outbreak of the war Lieutenant Goodden was senior resident medical officer at the Bristol Royal Infirmary, but almost directly the forces were mobilised he volunteered for active service, and had been at the front for many months. He was attached to the 2nd Battalion Royal Irish Regiment, and had been previously wounded on the Aisne, a cigarette case, it is said, preventing what would in all probability have been a fatal result. Lieutenant Goodden will be much missed in medical circles at Bristol, for he was one of the most popular "residents" ever holding office at the Bristol Royal Infirmary, and much sympathy is felt for his family.

Plymouth Medical Men and Military Service.

A largely attended meeting of medical men was held in Plymouth on May 13th to consider the call of the War Office for whole-time or part-time military service. Colonel Jones, Assistant Director of Medical Services, who had been deputed by the Deputy Director of Medical Services at Salisbury to be present, was in attendance. The chairman, Mr. R. Jacques, remarked that the War Office would receive more applications if commissions were granted in accordance with age and experience. Some medical men stated that they had written to the War Office some time ago, and had heard nothing more of the matter. Eventually it was decided to circularise the local medical profession, and a committee was appointed to consider the replies and suggest what means could be provided for dealing with the practices of those who volunteered for the work.

Hospital Saturday at Plymouth.

May 15th was observed as Hospital Saturday in Plymouth, when a strong appeal was issued to the local working people for the support of the South Devon and East Cornwall Hospital. The institution had a deficit balance of £2430 at the close of 1914.

The Cornwall County Council and the Treatment of Tuberculosis.

At the last meeting of the Cornwall County Council it was decided to purchase Castle-an-Dinas, at St. Columb Major, as a sanatorium for the treatment of tuberculosis, provided the Local Government Board would give financial assistance. The institution will accommodate 60 patients, and is situated on the south side of a hill about 600 feet above sea level. The cost of the scheme is estimated at £8000.

May 18th.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned Staff Surgeons have been promoted to the rank of Fleet Surgeon:—Dated May 15th: Samuel Henry Woods, Percy Temple Sutcliffe, John Percival Handel Greenhalgh, Edward Theodore Burton, Robert Hughes, Nelson Joseph Roche, Herbert Lyne Geoghegan, John Henry Lightfoot, and Penry Garnons Williams.

The undermentioned Surgeons have been promoted to the rank of Staff Surgeon:—Dated May 14th: Campbell Ross, Cecil Robert Morshead Baker, George Gordon Vickery, and Henry Dennis Drennan.

The undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet:—Dated May 11th: Robert Tennent and Basil Sampson. Dated May 12th: Howard James Bates.

ARMY MEDICAL SERVICE.

John Atkins to be temporary Colonel (dated Oct. 20th, 1914).

Temporary Major Cuthbert S. Wallace, from Royal Army Medical Corps, to be temporary Colonel (dated April 29th, 1915).

ROYAL ARMY MEDICAL CORPS.

The undermentioned are granted temporary rank whilst employed at the Norfolk War Hospital:—Dated April 22nd: As Lieutenant-Colonel: David George Thomson. As Major: Alexander Murchison Humphry, Charles Noon, and John Spence Law.

Temporary and Honorary Captain Cyril Alfred Rankin Nitch is granted the temporary and honorary rank of Major whilst serving with the British Red Cross Hospital, Netley (dated April 29th).

The undermentioned are granted temporary rank whilst employed at the Beaufort War Hospital, Bristol:—Dated May 1st: As Lieutenant-Colonel: James Vincent Blackford. Dated May 1st: As Major: John Robert Parry Phillips and Alexander McLean Cato. Dated April 17th: Frederick Sherman Toogood to be temporary Major whilst employed at the Lewisham War Hospital.

The undermentioned to be granted temporary rank whilst serving with the County of London War Hospital:—Dated May 1st: As Lieutenant-Colonel: John Robert Lord. Dated May 1st: As Major: Norcliffe Roberts and Reginald George Riches. William Dewey Duncombe to be temporary Major whilst serving at the City of London War Hospital (dated May 1st). Christopher Thackery Parsons to be temporary Major whilst serving at the Fulham War Hospital (dated May 1st). Edward Llewellyn Zenas Fickling to be temporary Lieutenant (dated Dec. 12th, 1914). Second Lieutenant Albert Edward Quine, from Reserve of Officers, to be temporary Lieutenant (dated May 4th).

The undermentioned Captains relinquish their temporary commissions on ceasing to serve with the Duchess of Westminster's War Hospital:—Dated May 18th: Sydney Scott and Thomas M. Body.

The undermentioned to be temporary Captains whilst serving with the Duchess of Westminster's War Hospital:—Dated May 18th: Forbes Fraser and John Wilfred Nunn.

The undermentioned to be temporary Lieutenants whilst serving with the Welsh Hospital: William MacAdam (dated April 26th) and David John Harries (dated May 10th).

The undermentioned to be temporary Majors: Alfred Lingard (dated April 9th) and temporary Captain Charles Coley Choyce (dated April 27th).

John Evans Phillips, late Captain, 1st North York Volunteer Artillery, to be temporary Captain (dated April 17th).

Harold Jossé Johnson, late Surgeon Captain, to be temporary Honorary Captain (dated May 19th).

The undermentioned to be temporary Lieutenants:—Dated March 1st: William Harle Stott. Dated March 15th: Arthur Cyril Albert Jekyll, Cedric Keith Cohen, and Eric Payten Dark. Dated March 17th: Keith Gemmell Colquhoun, Clive Travers Stephen, Henry Cecil Colville, and Alan Pryde. Dated March 19th: Charles Francis Drew. Dated March 23rd: Edward Rogerson, Louis Michael Pigott, Reginald Blockley Lucas, and William Heitland Godby. Dated April 21st: John Wright Turner, Thomas Wright, Arthur George James Thompson, Thomas Warner, Walter Charles Blackham, Walter Dymock Perry, George Hugh Culverwell, Robert Wilson Buchanan, William Penberthy, Isidore Jack Block, and Thomas Gilcriest. Dated April 22nd: James Boyd, Arthur Thomson Marshall, John Brunton, Barrington William Mudd, Ray Cecil Phelps, Harry Lovett Cumming, and James Hamilton Bogan. Dated April 23rd: James Lawson Whateley, John Hay Heddle, Ivan Whiteside Magill, Charles Gibson, Edmund Sheppard Cuthbert, John Moir MacKenzie, James Murdoch MacKay, Donald McDonald McIntyre, and Thomas Ruddock-West. Dated April 28th: Thomas Gee Williams.

SPECIAL RESERVE OF OFFICERS.

Supplementary to Regular Units or Corps: Royal Army Medical Corps.—The undermentioned Lieutenants (on probation) are confirmed in their rank: John R. Crolius and Robert H. Williams.

TERRITORIAL FORCE.

Army Medical Services.

Major Charles J. Martin, from Attached to Units other than Medical Units, to be Deputy Assistant Director of Medical Services, 2nd London Division.

Lieutenant-Colonel Ernest B. Dowsett, from 5th London Field Ambulance, to be Assistant Director of Medical Services, 2nd London (Reserve) Division, with the temporary rank of Colonel.

Royal Army Medical Corps.

2nd East Anglian Field Ambulance: Lieutenant Arthur Edwin Tait, from 2nd Northumbrian Field Ambulance, to be Lieutenant.

2nd Home Counties Field Ambulance: Henry Travers Jones to be Lieutenant.

2nd North Midland Field Ambulance: Major Richard M. West to be temporary Lieutenant-Colonel. Captain Joseph F. Dixon to be temporary Major.

1st Northumbrian Field Ambulance: Captain George H. Spencer to be temporary Major.

2nd Northumbrian Field Ambulance: Henry Stonehouse to be Lieutenant.

2nd Wessex Field Ambulance: Ernest Hall Scholefield to be Lieutenant.

3rd Wessex Field Ambulance: Captain Harold W. Read, from Attached to Units other than Medical Units, to be Captain.

2nd Highland Field Ambulance: John Moir to be Lieutenant.

London Mounted Brigade Field Ambulance: John Peers MacLulich (late Captain, South African Medical Corps) to be Captain (temporary).

South-Eastern Mounted Brigade Field Ambulance: Lieutenant Charles E. Silvester to be Captain. Alexander Graham Speirs Logie to be Lieutenant.

1st Eastern General Hospital: William Lombard Murphy to be Captain, whose services will be available on mobilisation.

2nd Northern General Hospital: The undermentioned to be Captains, whose services will be available on mobilisation: Carlton Oldfield, Leonard Alfred Rowden, Alfred Gough, Henry Harold Greenwood, Joseph Albert Blayney, Arthur Ellison, and Frederick William Marshall Greaves.

Highland Casualty Clearing Station: Captain Alexander Don, from 1st Scottish General Hospital, to be Major (temporary). James Davidson to be Lieutenant.

South Midland Casualty Clearing Station: Astley Bennett Prosser to be Lieutenant.

Highland Divisional Sanitary Section: Captain James M. McQueen, from 1st Scottish General Hospital, to be Captain.

2nd London Sanitary Company: Frederick George Rose to be Lieutenant.

3rd London General Hospital: Lieutenant Alfred Hope Gosse to be Captain on the permanent personnel.

1st Scottish General Hospital: Ian Gordon Bisset to be Lieutenant.

1st Southern General Hospital: Lieutenant-Colonel Harry G. Barling is seconded.

3rd Southern General Hospital: Arthur John Drew to be Captain, whose services will be available on mobilisation.

Attached to Units other than Medical Units.—To be Majors: Surgeon-Major Percival E. Barber, from West Riding Royal Horse Artillery, and Surgeon-Captain Alfred Robinson, from 5th Battalion, The York and Lancaster Regiment. William Appleyard (late Captain, 6th Battalion, The Prince of Wales's Own (West Yorkshire Regiment)) to be Captain. To be Lieutenants: Edgar Babst (late Lieutenant, 5th Battalion, Northumberland Fusiliers), Andrew Lowry McCully, John David Jones (late Lieutenant, 4th Battalion, The Welsh Regiment), and Samuel Shepheard. Lieutenant Charles W. Wirgman is seconded.

COUNCIL OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.—Mr. Alexander Blayney, F.R.C.S. Irel., has been elected a member of the Council of the Royal College of Surgeons in Ireland in room of the late Sir John Lentaigne. Mr. Blayney, like his predecessor, is a member of the staff of the Mater Misericordiæ Hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8117 births and 4954 deaths were registered during the week ended Saturday, May 15th. The annual rate of mortality in these towns, which had steadily declined from 19·9 to 15·5 per 1000 in the five preceding weeks, further fell in the week under notice to 14·2 per 1000 of their aggregate population, estimated at 18,136,180 persons at the middle of last year. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 17·2, against a corresponding rate of 18·1 per 1000 in London. Among the several towns the death-rate last week ranged from 5·2 in Ilford, 7·2 in Gloucester, 7·3 in Ealing and in Great Yarmouth, 7·7 in Enfield, and 7·9 in Wimbledon, to 22·0 in Bury, 22·4 in York, 22·5 in Lincoln, 24·2 in Sunderland, and 31·8 in Middlesbrough.

The 4954 deaths from all causes were 429 fewer than in the previous week, and included 484 which were referred to the principal epidemic diseases, against 711 and 557 in the two preceding weeks. Of these 484 deaths, 238 resulted from measles, 105 from whooping-cough, 57 from infantile diarrhœal diseases, 48 from diphtheria, 25 from scarlet fever, and 11 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·4, or 0·2 per 1000 less than in the previous week. The deaths attributed to measles, which had been 389, 392, and 276 in the three preceding weeks, further fell to 238 last week, and caused the highest annual death-rates of 2·0 in Salford and in Sheffield, 2·4 in Barrow-in-Furness, 2·6 in Coventry, 3·8 in Wolverhampton, 4·8 in Sunderland, 6·1 in Walsall, and 6·6 in Middlesbrough. The deaths referred to whooping-cough, which had decreased from 167 to 121 in the five preceding weeks, further fell to 105 last week; the highest death-rates from this cause were 1·2 in Walthamstow, 1·6 in Acton and in St. Helens, 2·1 in Middlesbrough, and 2·3 in Wigan. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 65, 73, and 67 in the three preceding weeks, further fell to 57 last week, and included 15 in London, and 3 each in Birmingham and Manchester. The deaths attributed to diphtheria, which had been 49, 56, and 51 in the three preceding weeks, declined to 48 last week, of which 11 occurred in London, 4 in Manchester, and 3 in West Ham. The deaths referred to scarlet fever, which had been 29, 34, and 30 in the three preceding weeks, further fell to 25 last week, and included 6 in London and 2 each in Willesden, Birmingham, Coventry, Manchester, Blackburn, and Leeds. The fatal cases of enteric fever, which had been 8, 12, and 12 in the three preceding weeks, were 11 last week, but showed no excess in any particular town.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2369, 2377, and 2384 at the end of the three preceding weeks, had decreased to 2332 on Saturday last; 270 new cases were admitted during the week, against 259, 316, and 307 in the three preceding weeks. These hospitals also contained on Saturday last 1174 cases of diphtheria, 186 of measles, 59 of enteric fever, and 12 of whooping-cough, but not one of small-pox. The 1255 deaths from all causes in London were 129 fewer than in the previous week, and corresponded to an annual death-rate of 14·5 per 1000. The deaths referred to diseases of the respiratory system, which had decreased from 469 to 289 in the four preceding weeks, further fell to 227 in the week under notice, but were 37 above the number recorded in the corresponding week of last year.

Of the 4954 deaths from all causes in the 96 towns 210 resulted from different forms of violence and 376 were the subject of coroners' inquests, while 1512 occurred in public institutions. The causes of 48, or 1·0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, and in 67 other smaller towns. Of the 48 uncertified causes of death, 10 were registered in Birmingham, 6 in Liverpool, 3 each in Gillingham, Stoke-on-Trent, Bootle, and Gateshead, and 2 each in Southend-on-Sea, Dudley, Nottingham, and Rotherham.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1175 births and 807 deaths were registered during the week ended Saturday, May 15th. The annual rate of mortality in these towns, which had been 18·5, 20·2, and 18·1 per 1000 in the three preceding weeks, further fell to 17·9 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 19·4, against a corresponding rate of 17·2 per 1000 in the large English towns. Among the several towns the death-rate last week ranged from 11·7 in Clydebank, 12·9 in Edinburgh, and 14·0 in Kirkcaldy, to 19·6 in Glasgow, 21·3 in Falkirk, and 27·6 in Motherwell.

The 807 deaths from all causes were 8 fewer than the number in the previous week, and included 117 which were referred to the principal epidemic diseases, against 150 and 142 in the two preceding weeks. Of these 117 deaths, 49 resulted from measles, 45 from whooping-cough, 9 from infantile diarrhœal diseases, 8 from diphtheria, and 6 from scarlet fever, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 2·6, against 1·4 per 1000 in the large English towns. The deaths attributed to measles, which had increased from 19 to 47 in the four preceding weeks, further rose to 49 last week, and comprised 40 in Glasgow, 5 in Aberdeen, 3 in Falkirk, and 1 Clydebank. The deaths referred to whooping-cough, which had declined from 90 to 65 in the four preceding weeks, further fell to 45 last week, of which 33 occurred in Glasgow, 4 in Aberdeen, and 3 in Edinburgh. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 12, 9, and 15 in the three preceding weeks, fell to 9 last week, and included 3 each in Glasgow and Edinburgh. The deaths attributed to diphtheria, which had been 6, 12, and 7 in the three preceding weeks, were 8 last week, of which 3 were registered in Glasgow. The 6 deaths referred to scarlet fever were 2 below the average in the earlier weeks of the quarter, and included 2 each in Glasgow and Aberdeen. In addition to the above deaths, a fatal case of typhus occurred in Dundee.

The deaths referred to diseases of the respiratory system, which had been 145, 153, and 118 in the three preceding weeks, slightly rose to 121 in the week under notice, and were 17 in excess of the number recorded in the corresponding week of last year. The deaths from violence numbered 26, against 25 and 23 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,212,380 persons at the middle of this year, 582 births and 438 deaths were registered during the week ended Saturday, May 15th. The annual rate of mortality in these towns, which had been 22·4, 19·1, and 19·9 per 1000 in the three preceding weeks, fell to 18·8 per 1000 in the week under notice. During the first six weeks of the current quarter the mean annual death-rate in these towns averaged 21·0, against corresponding rates of 17·2 and 19·4 per 1000 in the English and Scotch towns respectively. The death-rate last week was equal to 21·9 in Dublin (against 14·5 in London and 19·6 in Glasgow), 15·1 in Belfast, 16·3 in Cork, 20·2 in Londonderry, 31·1 in Limerick, and 19·0 in Waterford, while in the 21 smaller towns the mean death-rate was 18·3 per 1000.

The 438 deaths from all causes were 25 fewer than the number in the previous week, and included 27 which were referred to the principal epidemic diseases, against numbers declining from 41 to 33 in the three preceding weeks. Of these 27 deaths, 10 resulted from whooping-cough, 8 from infantile diarrhœal diseases, 4 from measles, 3 from diphtheria, and 1 each from enteric fever and scarlet fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·2, against corresponding rates of 1·4 and 2·6 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had been 20, 9, and 9 in the three preceding weeks, were 10 last week, and comprised 5 each in Dublin and Belfast. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 5, 10, and 9 in the three preceding weeks, were 8 last week, of which 6 were recorded in Dublin. The fatal cases of measles, which had been 13, 11, and 10 in the three preceding weeks, further fell to 4 last week, and comprised 2 each in Belfast and Portadown. Of the 3 deaths attributed to diphtheria, 2 were registered in Dublin and 1 in Belfast. The fatal case of enteric fever was recorded in Sligo, and that of scarlet fever in Waterford.

The deaths referred to diseases of the respiratory system, which had steadily declined from 158 to 76 in the five preceding weeks, rose to 82 in the week under notice. Of the 438 deaths from all causes, 138, or 32 per cent., occurred in public institutions, and 4 resulted from various forms of violence. The causes of 16, or 3·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the large English towns the proportion of uncertified causes did not exceed 1·0 per cent.

THE death by fever in Upper Nigeria of Dr. John Beattie, of the West African Medical Service, is announced.

DIFFICULT LABOUR AND DENTAL DEFORMITIES.

To the Editor of THE LANCET.

SIR,—In your issue of April 24th I notice a request by Mr. J. F. Colyer asking for details and models of dental deformities presumably caused by obstetric operations. As I have been since 1906 carefully collecting such statistics for a future communication and have not heard of others engaged in this inquiry, I believe I am the only observer who possesses the information which Mr. Colyer desires, but this is, obviously, at present not at Mr. Colyer's disposal.

I do not believe Mr. Colyer will be able to obtain much reliable material as a result of his impetuous appeal in your columns, for as these deformities do not fully develop until the permanent teeth have erupted, a period of more than seven years must elapse after birth before the exact nature of the deformity is known. It is unlikely that the accoucheur who was present at the birth would take models of the denture, or even associate the deformity with the difficult labour. I am sure Mr. Colyer will have to adopt my plan of patiently following up each case as it presents itself, interrogating the mother, and if possible examining the medical attendant's records. This is a very slow process, but it is the only way to obtain sufficient material for proof; the field is so entirely new and tabulated records will have to be made. Mr. Colyer has under his own care one of the most valuable cases in this connexion. At the annual meeting of the International Medical Congress in 1913 at a demonstration meeting at the Dental Hospital he exhibited a boy, an extreme case of mandibular protrusion. He told us this was nothing, just an ordinary case of mandibular protrusion. In a conversation I had with the mother before the demonstration, and in reply to my inquiry, she informed me that the labour was very prolonged and dangerous, the head being in the *left side*. It was evident that this was a case of transverse presentation, and that the operation of turning had been performed; to do this the operator had exerted sustained and forcible traction by means of the mandible, forcibly straightening this cartilaginous structure at the angle and increasing its length; from this injury it had not recovered. Possibly the relation by the mother to Mr. Colyer of our conversation has served to interest him in this inquiry.

I cannot claim to be the first in this field; this honour is due to Dr. L. S. Chilcott, whose paper, An Obstetrical Deformity of the Mandible, appeared in the *Dental Cosmos* in March, 1906, but I do believe I am the first to systematically study each case of these deformities from the obstetrical standpoint. Dr. Chilcott's case was one of breech presentation, and he contended that the deformity was caused by great pressure upon the angle by the bone of the pelvic outlet, producing an open bite. The angle of the mandible in this case was so obtuse that it had almost disappeared.

The above are both cases of mandibular deformity due to malpresentation. Superior protrusion is much more common, and I have suspected for some time that a small pelvic outlet and the use of the midwifery forceps, the lateral pressure of which is very powerful, is responsible for many cases of this condition.

My records show that of those cases I have been able to trace the forceps were used in 80 per cent.

I am, Sir, yours faithfully,

Denmark Hill, S.E., May 12th, 1915. FREDERICK LONNON.

MENTAL TREATMENT BILL.

To the Editor of THE LANCET.

SIR,—My attention has been called to a letter from Dr. S. E. White in your issue of May 8th. This letter is based on a misconception of the law and the results following from the law, which were clearly explained in the Memorandum to Lord Russell's Bill mentioned in the letter.

By Section 315 of the Lunacy Act, 1890, it is a misdemeanour to take charge of, receive to board or lodge or to detain a lunatic or *alleged* lunatic in an unlicensed house; and it is made unlawful, except under the provisions of the Act, for any person to receive or detain two or more lunatics in any house unless the house is an institution for lunatics or a workhouse. The case law shows clearly that it is no defence to a prosecution to show that the accused was quite unaware of the fact that a patient was a lunatic or *alleged* lunatic. The practical result is that very few people indeed can be found willing to receive "borderline" cases, for the risk of prosecution is too great, and if prosecution takes place conviction almost inevitably follows. It is futile to criticise a proposal to legalise treatment which is voluntary as regards the patient, when the law makes it a crime to receive or take charge of an alleged lunatic irrespective of the question whether he consents or not.

Lord Russell's Bill was intended to enable treatment of "borderline cases" without fear of prosecution. The rest of the Bill was machinery to prevent abuse of such permission. Legislation is imperatively necessary for this purpose.

I am, Sir, yours faithfully,

ROLAND BURROWS.

Brick Court, Temple, E.C., May 13th, 1915.

⁂ The Bill was formally withdrawn this week and some explanation of the views of the Government appeared in a statement made by Mr. Cecil Harmsworth.—ED. L.

THE DETECTION OF PROJECTILES IN WOUNDS BY THE ELECTRO-MAGNET.

To the Editor of THE LANCET.

SIR,—I hasten to draw the attention of my colleagues employed at hospitals for the wounded to the excellent results obtained from the methods adopted by Professor Bergonié, who searches for projectiles by means of an electro-magnet with alternating current (fonctionnant sur courant alternatif).

When a magnetic body is found within the field of the apparatus a quite particular vibration is produced which the hand easily recognises, and which emanates from the foreign body itself. If this foreign body is situated in the tissues the maximum point of vibration corresponds with the projection of this body upon the superfices (à la projection de ce corps sur la superficie). The intensity of the vibration apprises us at the same time of the volume and situation in point of depth of the body. The process is rapid, simple, cleanly, and allows the surgeon to inform himself at every stage of his operation.

I have had the privilege of experimenting with this apparatus under the direction of Professor Bergonié himself in a hospital at the front, and the results have far surpassed our expectations. I feel it my duty to make it known as a matter of urgent importance. I know how much sudden enthusiasms should be suspected in the case of a new method. But at this time when inventions for demolishing humanity seem to be attaining perfection every day, one can claim some credit for an invention which promises, though it be novel, to alleviate suffering.

I hold myself at the disposal of my colleagues for all additional explanations.

I am, Sir, yours faithfully,

GUSTAVE MONOD,
Médecin Major, M.D. Paris, M.R.C.P. Lond., &c.
Ambulance 10, Corps d'Armée 6, Secteur 154.

THE MEDICAL DEFENCE UNION AND THE NATIONAL INSURANCE COMMISSIONERS.

To the Editor of THE LANCET.

SIR,—In order to test the validity and legality of the regulations of the National Insurance Commissioners in the matter of surcharging panel practitioners for alleged extravagance in prescribing for insured persons, the Medical Defence Union has, on behalf of two of its members concerned, caused to be issued writs in the High Court. I need hardly point out to your readers in general, and to those on the panel in particular, the importance of these actions, which I trust will be before His Majesty's judges within a comparatively short time. The Medical Defence Union has already been successful in every action or appeal brought in respect of legal questions under the Act, and is engaged daily in working, *inter alia*, for the protection of those who have joined the panel willingly or unwillingly.

Those who have not joined the Medical Defence Union should do so without delay, as this year will be critical in the history of panel practitioners, and they cannot afford to be without its protection.

I am, Sir, yours faithfully,

A. G. BATEMAN,
General Secretary.
4, Trafalgar-square, W.C., May 15th, 1915.

PRELIMINARY EXPLORATION OF THE PELVIS IN CERTAIN CASES OF ACUTE APPENDICITIS.

To the Editor of THE LANCET.

SIR,—Professor W. Sampson Handley, in his interesting lecture on Ileus Duplex in your issue of May 1st, advocates exploration of the pelvis, through a preliminary median sub-umbilical incision, in cases where there is doubt as to whether the infection has spread from the right iliac fossa to the pelvis. On the principle that in dealing with a possible extension of the infection beyond the iliac fossa it is always better to know than to guess, the writer has for some years employed a procedure similar, except in the detail that a 2-inch incision is made over the lower portion of the left rectus muscle, the fibres of which are split, with the object of preventing post-operative hernia.

A recent case was that of a young man who when first seen had advanced appendicitis and was ashen grey from toxæmia. Preliminary exploration through the left lower rectus showed gross infection of the lower abdomen. Large drainage tubes through the left rectus, the right iliac fossa and loin, combined with the Fowler position and many pints of saline solution given per rectum by Murphy's method, resulted in interrupted recovery with total absence of incisional herniæ. Preliminary exploration through the left lower rectus takes but a few minutes, changes doubt into certainty, and appears to have no serious drawbacks.

I am, Sir, yours faithfully,

Plymouth, May 4th, 1915. C. HAMILTON WHITEFORD.

THE TREATMENT OF CORNS.

To the Editor of THE LANCET.

SIR,—I have read with much interest the letter of Mr. Paul Bernard Roth in your issue of May 15th. Some years ago I was an absolute martyr to corns, one particular corn giving me most excruciating annoyance when I walked. I conceived the idea of wearing two pairs of socks, a thin pair (merino) next the skin and a thick woollen pair over these, and I took particular care to have boots with thick soles "made to the foot" and would not have my "foot made to the boot." In a very short time my corns disappeared and I have not been troubled since, but my friends laugh at my boots. I now find walking a pleasure.

I am, Sir, yours faithfully,

May 14th, 1915. D.P.H.

Obituary.

BERTRAM HERBERT LYNE STIVENS,

M.R.C.S., M.D. BRUX.

Dr. Bertram Herbert Lyne Stivens passed away at his residence, 107, Park-street, Grosvenor-square, London, on Sunday afternoon, May 9th. He was in his usual health up to Friday, April 30th, when a feverish attack with sore-throat supervened. On Monday, May 3rd, feeling somewhat better, he attended to his professional duties, as also on the following day. On Tuesday evening, May 4th, the inflammation of the throat returned and became rapidly worse, and on Sunday afternoon he died from streptococcal pharyngitis with œdematous laryngitis and pyæmic infection. This is always rapid and often fatal, particularly in a constitution which is not strong. In spite of his manly figure and fine presence Dr. Stivens had visibly failed, we are informed by a personal friend of his, since the death of a beloved daughter two years ago.

Dr. Stivens was born at Birkdale in 1855. He spent his early life in Cheshire and was educated at Bunbury Grammar School. Later he studied abroad at Stuttgart and Heidelberg University. He then decided upon a medical career and entered the medical school of King's College Hospital in 1877, being some four or five years older than most of the men of his year. He had a very successful career as a student, and proceeded to the tenure of two residential posts at that time much coveted. He was first house accoucheur under the late Dr. W. S. Playfair, and later house surgeon to the great Lister himself at the time when the operating theatre used to be crowded with visitors to learn the new antiseptic methods. These two posts under such masters were sufficient to lay the foundation of a talent for accurate and conscientious observation to which he owed his success in practice.

Although Dr. Stivens might well have aspired to consulting work, the opportunity of joining an old-established practice in the West-end decided him to go direct from the wards to family practice in Kensington Gardens-square. Here his success, at a comparatively early age, was both rapid and easy. It was easy because to his knowledge and skill he was able to add the manner which is such a large factor of success in private practice. His manner was not a pose, but was the expression of a frank, sympathetic, genial, and hearty nature which took the deepest and most sincere interest in his patients and his friends. He later moved from Kensington Gardens-square to Park-street, Grosvenor-square, where his practice still further rapidly increased, and where he had the honour of attending members of the Royal family. He was an accomplished linguist, and his studies abroad stood him in good stead in medical practice. He included amongst his friends many of the most distinguished continental physicians; he often visited their clinics, and introduced into this country several new methods of investigation and treatment which were being developed on the continent. Thus he appreciated the importance of the analytical investigations in gastro-intestinal diseases which were being undertaken in France and Germany, and he was perhaps the first to carry out in this country these methods of investigation, and to utilise them in guidance for appropriate medical treatment. He was familiar with the operation for removal of enlarged tonsils and adenoids in suitable cases long before it was generally practised in this country, and was among the first in performing this useful operation here in suitable cases. If he had aspired to it he might certainly have risen to more scientific eminence in his profession, since he had great gifts and especial knowledge and experience. He was content, however, with a less public and perhaps more satisfactory career, for it may be truly said of him that he loved to go about doing good.

Circumstances made him early in life independent of his profession, but his love for the practice of his art induced him to continue it long after other men would have given it up. He was a keen sportsman and fond of country life, and he was happy in his country home when the exigencies of his busy life permitted him to stay there. He was a devoted husband and father, and a most loyal and hospitable friend. His friend and patient, Sir Rider Haggard, suggests for his epitaph the words "Our Beloved Physician," and this expresses the regard which all his patients without exception felt towards him.

Dr. Stivens married Belita, the daughter of the late Mr. George Drabble, of Pembridge-square, W. The sympathy of the medical profession and of a large circle of friends will go out to his widow and two daughters in their bereavement.

A New Route to Italy.—The Paris, Lyons, and Mediterranean Railway opened to traffic on May 16th the new line "Frasne-Vallorbe," the construction of which was commenced at the end of the year 1910. This line has a double track of about 24 kilometres (15 miles) in length, 22 of which are in French territory. It branches off from the Dijon-Pontarlier line at the station of Frasne, and crosses one of the most picturesque districts of the French Jura. It serves the two beautiful lakes of Remoray and Saint Point, penetrating the "Mont d'Or" through a tunnel of 6670 yards in length, and joining again the Pontarlier-Lausanne line at Vallorbe. The improvements carried out have resulted in a gain of from 45 minutes to one hour on the journey between Paris and Lausanne. The large radius of the curves is favourable for speed, and, in winter, the tunnels and pine forests through which the line passes are a protection against snowstorms. With these improvements the P.L.M. line will, more and more, become the traveller's highway between Paris and Italy.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

The Central Committee.

A meeting of the Central Committee was held on Thursday, May 13th, when Sir Rickman Godlee, the chairman, announced that he had received from Dr. Péchère, President of the Aide et Assistance aux Médecins et Pharmaciens Sinistrés, a formal receipt for the money sent by the Fund to Belgium for distribution, and it was agreed to forward the same amount on future occasions, and at intervals, as soon as particulars of distribution had been ascertained.

The treasurer, Dr. Des Vœux, reported that he had placed further sums of money on deposit, and noted that the subscription lists had now begun to get smaller. It was the feeling of the Committee that this might be due to the fact that much of the money collected had not yet been spent, but it was hoped that the urgent need of the cause would not be lost sight of. At the rate of expenditure sanctioned by the Committee, the Fund, at its present figure, will not last very long, and it is particularly desirable that when hostilities cease there should be some money in hand to form a nucleus for an international scheme of reinstatement after the war.

Clothes Required.

Gifts of clothes would be welcomed by the Committee. The supply is running short, and assistance in this direction is often very valuable to and highly appreciated by our Belgian colleagues and their families. All parcels of clothes should be addressed to Mrs. Colebrooke, Wesleyan Training College, Horseferry-road, London, S.W.

Birmingham Local Committee.

This committee held its final meeting on Tuesday, May 11th, with Professor Barling in the chair, in order to receive reports from Professor R. Saundby and Mr. F. Smith. The accounts and vouchers had been submitted to Sir Thomas Barclay, who had audited them and given certificates of their accuracy. The total amount collected was £526 5*s.* 3*d.*, the whole of which has been remitted to Dr. Des Vœux, the honorary treasurer of the Fund in London. All expenses have been defrayed locally, and there has been no deduction from the amounts subscribed.

Further subscriptions will be forwarded to Dr. Des Vœux, and acknowledged as usual by publication of the names of the donors in the medical journals.

The Week's Subscriptions.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, are as follows:—

	£	*s.*	*d.*
Bucks Division, B.M.A. (per Dr. A. E. Larking)—			
Dr. W. H. Square ...	1	1	0
Dumfries and Galloway Division, B.M.A. (per Dr. J. Dewar Robson, Hon. Sec.)—			
Dr. Scott	0	10	6
Dr. Bryson	0	10	6
Dr. Chalmers	1	1	0
Dr. Dunlop	1	1	0
Dr. McKie	0	10	6
Dr. Shaw	1	1	0
Dr. J. Dewar Robson...	2	2	0
Dr. Brown	1	1	0
Stewartry of Kirkcudbright Secondary Education Committee (per Dr. J. Gair Johnston, School Medical Officer)	1	1	0
Tower Hamlets Division, B.M.A. (per Dr. W. H. F. Oxley, Hon. Sec.)—			
Dr. H. Hamilton Mack	0	10	6
Nottingham and Notts Pharmaceutical Association (per Mr. H. P. Middleton)	5	5	0
Hants County Pharmaceutical Association (per Mr. S. G. Bartlett)	0	10	6

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear in the casualty lists published since our last issue:—

Killed: Major J. Woods, I.M.S., Lieutenant Henry Wyndham Goodden, (attached 2nd Royal Fusiliers), Lieutenant M. Pern, Captain S. Field, all of the R.A.M.C. Captain Field was the son of Mr. G. P. Field, the well-known aurist.

Died of wounds: Lieutenant John Aquila MacMahon, R.A.M.C.

Wounded: Captain E. A. Sutton, Lieutenant E. H. Griffin, Lieutenant C. W. Sparks (attached Royal Irish Fusiliers), Lieutenant A. N. Hooper (attached 2nd East Yorks Light Infantry), Lieutenant E. C. Linton, Major J. S. Y. Rogers (attached 4th Black Watch T.F.), Captain W. Rogers (attached 5th Cheshires), Lieutenant F. H. Sprague, all of the R.A.M.C. Captain J. W. B. Bean, Australian Medical Service.

Missing: Captain P. G. M. Elvery, R.A.M.C. (attached 1st Yorks Light Infantry), Fleet-Surgeon George A. Waters, R.N., of the *Goliath.* Lieutenant J. A. Stenhouse, R.A.M.C., previously officially reported missing, is now unofficially reported a prisoner of war.

Both the medical officers of the *Lusitania*, Dr. J. F. McDermott and Dr. Joseph Garry, were among the drowned.

Captain Eric Evans (4th Royal Welsh Fusiliers), who has died of his wounds, was a son of Mr. E. D. Evans, M.R.C.S., J.P., of Wrexham, and had nearly completed his medical course when the war broke out and the regiment in which he held a lieutenant's commission was mobilised.

DEATHS AMONG THE SONS OF MEDICAL MEN.

Already many medical men have had the sad experience of losing their sons in the war. The late Dr. Lewis Jones, Sir Wilmot Herringham, Dr. Norman Moore, Dr. H. D. Rolleston, Sir Pardey Lukis, Sir James Barr, and Mr. W. H. Battle are among those who have thus paid with their dearest possessions the price of patriotism, and other names will occur to our readers. During this month a heavy toll of this kind has been exacted from members of our profession, the following deaths being announced in recent casualty lists. Lieutenant T. M. Garrod, second son of Dr. A. E. Garrod; Second Lieutenant R. T. Shaw, elder son of Dr. Lauriston Shaw; Lieutenant C. B. Spence, younger son of Dr. James B. Spence, of Burntwood; Second Lieutenant R. Fazan, youngest son of Mr. C. H. Fazan, of Wadhurst; Second Lieutenant E. H. Orton, youngest son of Dr. G. H. Orton, of Kensington; Second Lieutenant A. H. S. Tuke, only son of Dr. T. S. Tuke, of Chiswick; Second Lieutenant H. W. Hodges, elder son of Mr. H. C. Hodges, of Watton-at-Stone; Captain T. R. Scott, eldest son of Dr. Thos. Rennie Scott, of Musselburgh; Second Lieutenant T. M. Bond was the son of Major T. M. Bond, attached R.A.M.C. Captain G. D. Mathew, whose death has also been reported, was the youngest son of the late Brigade-Surgeon Lieutenant-Colonel R. G. Mathew; and Second Lieutenant F. P. Trevor was the only son of the late Mr. A. T. H. Trevor, of Beaumaris.

THE MEDICAL RESEARCH COMMITTEE (NATIONAL HEALTH INSURANCE) AND WORK IN CONNEXION WITH THE WAR.

An interim report has been issued on the special work in connexion with the war at present undertaken by the Medical Research Committee of the National Health Insurance Commission.

It is addressed by Dr. W. Morley Fletcher, F.R.S., Secretary of the Medical Research Committee, to the Right Hon. E. S. Montagu, M.P., Chairman of the National Health Insurance Joint Committee, and runs as follows:—

As desired, I submit herewith a *précis* of the work already undertaken by the Medical Research Committee in connexion with the war. This work is, of course, additional to the schemes of research previously organised by the committee in other directions independently of the war, which is still in progress, except in so far as it has been thought expedient or necessary to suspend it in favour of work of greater urgency.

Mount Vernon Hospital Building, Hampstead.

The building and grounds which the committee had acquired at Hampstead for conversion into the laboratories of their central institute were placed by the committee upon the outbreak of war at the disposal of the War Office. For some months the building has been in use as a military hospital, for which its nature and position give it exceptional fitness.

Compilation and Analysis of the Medical Statistics of the Military Forces.

The whole resources of the Statistical Department of the committee, under the direction of Dr. John Brownlee, have been placed at the disposal of the War Office, and this department is now carrying out, on behalf of the Army Council, the compilation of the statistics of the sick and wounded from the military forces. At a later date the department will undertake the analysis of the collected statistics. For the purposes of this work the committee have taken special premises, which they have equipped with the necessary furniture and staff. Card indices are being compiled from the returns provided from official sources, and typists are engaged at the military hospitals throughout the country to secure the rapid collection of information from the hospital books. The committee are indebted to the London Divisional Office of the Labour Exchanges under the Board of Trade for the rapid and economical organisation of these women workers. In the view of the committee the compilation and analysis of these medical statistics, in the circumstances of the present war, will have a general value in providing information in various directions with regard to the health and stamina of the male population of these islands, in addition to its particular value from the special points of view of military requirements and of the Army Medical Service. The services of Dr. Brownlee and his assistants have also been lent for a statistical investigation of the male population of the German Empire and its present distribution, which has been undertaken in connexion with military purposes.

Pathological Work at Military Hospitals.

The committee have assisted the War Office in supplying pathologists and bacteriologists for work at military hospitals in this country. In general, where commissioned officers have been obtainable for this work, grants have been made for the supply of special apparatus for particular purposes not falling within the ordinary routine of hospital work. At many of the centres grants have been made for part-time work by pathologists without commissions, whose work in some cases is carried out in adjacent laboratories belonging to university or other bodies. In certain cases the committee have equipped special laboratories within military hospitals for the purposes of routine work or for the conduct of special inquiries, or both.

Special Inquiries.

Work by the Committee's Bacteriological Department.—The whole services of the Bacteriological Department under the direction of Sir Almroth Wright, who had accepted appointment by the committee as director of that department before the outbreak of war, have been applied to purposes of military importance. During the first month of the war Sir Almroth Wright and his staff appointed by the committee gave the whole of their time to assist at the inoculation department of St. Mary's Hospital in the preparation of vaccines for the use of H.M. Forces, and during that time very large quantities of antityphoid vaccine and antisepsis vaccine were supplied, as they have continued since to be supplied by the inoculation department, to the Admiralty, the War Office, and the French and Belgian armies. Sir Almroth Wright in September was appointed consulting physician to H.M. Forces Overseas, with the rank of colonel, and he, with Captain Douglas and Lieutenant Parry Morgan, have since prosecuted important researches at Boulogne, bearing upon the treatment of infected wounds. Preliminary results of these inquiries have already been published and have led to the circulation by the War Office of a memorandum to all medical officers with the forces at home or abroad with regard to their application in practice. The Medical Research Committee have also maintained three members of Sir Almroth Wright's staff in work under his direction at the inoculation department of St. Mary's Hospital. It is proposed in the immediate future to add to Sir Almroth Wright's staff at Boulogne two senior bacteriologists to follow special lines of research arising in connexion with his own work. In accordance with the rule laid down for the Civil Service, every member of the committee staff to whom H.M. commission as a military officer has been given receives the amount of his salary from the committee less the amount of his military pay.

Cholera expedition to Galicia.—Dr. John Freeman, with an interpreter, was sent by the committee last autumn to Galicia, where he enjoyed the temporary rank of lieutenant-colonel in the Russian Army, in order to investigate the various strains of cholera infection, endemic or epidemic, in that district, and to bring to this country cultures of the chief strains. It appears important to the committee that these strains should be available for the preparation of vaccines in view of the possible eventuality of a transference of infection to the Allied Forces in the western theatre of war. The results of the expedition were placed at the disposal of the inoculation department of St. Mary's Hospital, which has been able already to supply large quantities of anti-cholera vaccines to the Serbian Government and to the British Forces in the Mediterranean area.

Bilharzia expedition to Cairo.—The committee are supporting by grant from the Medical Research Fund the expenses of inquiries near Cairo by Colonel Leiper and two assistants. This work has in view the application and extension of the results of recent discoveries with regard to the life-history of the species of bilharzia which is endemic in the Nile delta with special reference to the prophylactic measures to be taken for the protection of the visiting forces.

Typhoid bacilli and paratyphoid bacilli, α and β.—Grants have been made for work at Oxford under the direction of Professor Dreyer for the development and application of methods securing accurate measurement of the agglutination reactions in typhoid and paratyphoid infections and for the study of the action of light rays of particular wave lengths used for the separation of bacillus typhosus or paratyphosus in mixtures of these with other organisms. In view of the results of this work the committee are supporting the simultaneous study of the same methods at Boulogne, London, Leicester, and Netley. Investigations of similar problems connected with these infections are being supported at Manchester under the direction of Professor Delépine.

Standardisation of emulsions and sera for agglutination tests (typhoid and paratyphoid).—The committee are engaged in establishing at Oxford, under the direction of Professor Dreyer, a department for the regular standardisation of emulsions and sera for agglutination tests. The standard emulsions and sera will be supplied to military hospitals for the convenience of bacteriologists and for the better coördination of results obtained by different observers at different times and places.

Antiseptics.—At Leeds the committee are supplying assistance to Professor Cohen for the preparation of new chemical substances of antiseptic value. Professor Cohen is working in conjunction with Dr. Carrel and Dr. Dakin, who are making clinical observations in France. At the London Hospital Medical College the committee are supporting the joint investigation by Dr. Fildes and Dr. Rajchmann, with Mr. Cheatle, at Haslar, into certain compounds of antiseptic value. At Edinburgh special inquiries into antiseptics, and into the infections of wounds, under the direction of Professor Lorrain Smith and Professor Ritchie, are also in progress.

Epidemic cerebro-spinal meningitis ("spotted fever").—The committee are supplying the War Office with the services of Dr. M. H. Gordon, temporary Major, who is directing the whole of the routine bacteriological work undertaken in this country in connexion with the study and control of this disease among the military forces. The committee have made grants to provide two assistants for Major Gordon at the central laboratory for cerebro-spinal meningitis established at the Royal Army Medical College, Millbank, and have further supplied assistance at Woolwich, Brighton, Exeter, Newcastle-on-Tyne, Cambridge, Manchester, Cardiff, Bristol, and Devonport for the completion of the whole scheme of distribution of workers organised by the War Office. The committee have initiated special research work by Dr. Colebrook and Dr. Tanner into the methods of sterilising positive "contacts," and this is in progress in the research wards supported by the committee in connexion with the inoculation department at St. Mary's Hospital. Another investigation into certain questions of the mode of infection and of spread of disease is also in progress at the Millbank laboratory.

Neurological Work at Military Hospitals.

The committee have endeavoured to arrange for the better coördination of the study and description by trained observers of the important groups of neurological cases at military hospitals. In conjunction with workers abroad, neurologists in London and at several provincial centres are now working upon a common plan, the committee providing certain printed forms, diagrams, and apparatus. A card index is being compiled for reference to the full clinical records in individual hands. In connexion with this scheme grants are already being made for part-time work by five or six uncommissioned physicians for assistance in the study of these cases.

Performance of Wassermann Tests.

It has been arranged for Wassermann tests to be made at a central laboratory for cases in certain military hospitals where the necessary facilities are absent.

Testing of Salvarsan Preparations.

The direction of the biological testing of salvarsan preparations manufactured in England and France and sold in this country under licence of the Board of Trade has been undertaken by the committee at the request of the Board. The tests are performed by experts approved by the committee and a certificate signed by the secretary of the committee is issued to allow the sale of each batch of which samples have passed satisfactorily the proper tests. The out-of-pocket expenditure incurred in the testing is charged to the manufacturers.

General.

Upon request from Colonel Sir William Leishman, in his capacity of Adviser in Pathology to the Expeditionary Force, reports have been obtained from expert sources upon particular questions, or special inquiries instituted, and the results have been or will be transmitted to him for use. Among the subjects already dealt with have been those of "trench rheumatism," prophylaxis for dysentery, and the prevention of fly-borne diseases.

The committee have made arrangements to assist medical officers working overseas in following the after-history of certain groups of cases after arrival in this country.

THE MEDICAL OFFICERS' ADMINISTRATIVE DUTIES IN RESPECT OF THE PERSONAL BELONGINGS OF THE WOUNDED.

A good deal of complaint has been made about the loss of personal belongings by the wounded during their transport to the rear. This has, of course, happened in every war, is happening undoubtedly in this one, and we are informed on high military medical authority is receiving the most anxious consideration on the part of the authorities to ascertain the cause with a view to its prevention.

From the letter of "An Officer" in the *Times* of May 6th, supported by other testimony, it would appear that the loss usually takes place not in the field but in the field ambulances and the clearing hospitals. He reached the field ambulance with all his belongings strapped to his person, and they were laid by his side during the night, but on his removal next day he was told that they could not be taken on the stretcher with him as it was "against the order." On his refusing to be moved without them, the medical officer in charge finally gave the required permission, and they reached the clearing hospital with him, and were again deposited alongside of him. The following morning the difficulty recurred, and he had "an extremely heated argument with the R.A.M.C. Captain on the subject," but eventually he succeeded in getting his way and he finally had the good fortune to reach his destination with his personal belongings, field-glasses, revolver, haversack containing his money, and so forth, in his possession. There is, however, considerable testimony that many less determined officers, or officers perhaps whose condition was too grave to render such opposition possible, have lost all their belongings. Indeed, one instance is related in the *Times* of the following day, of an officer who, having thus lost all his equipment, claimed, and was granted, £50 compensation from the War Office. Whichever way it is looked at, the wastage thus involved is deplorable. To replace field-glasses, revolvers, and other necessary equipment is a serious and unnecessary tax upon the financial resources of the individual officer; on the other hand, if all officers thus despoiled are to be compensated out of public money it will become an impost as wanton as it should be unnecessary on the public who have to pay the piper. Now, in part, of course, blame attaches to all officers who do not have their property ineffaceably engraved with their name, rank, and regiment, to facilitate their eventual return in case of their going astray, and we are informed that this is the case in very many instances. On the other hand, it is noticeable that the loss is attributed to "orders" about not carrying things on stretchers, and their rigid and perhaps undiscriminating enforcement by medical officers in charge. It is quite understandable that the carrying of heavy packages on the stretcher should be forbidden for obvious reasons; but surely the personal military equipment of an officer should be allowed to accompany him. It is possible that the instances are due to a misapprehension on the part of the medical officer of the significance of the order. This is one of the multitudinous but inevitable extra professional duties of the medical officer which can be mastered only by military training, a fact that is entirely overlooked by those medical men who seem to think that the sole difference between a military medical officer and a medical man exercising his profession in civil life is that the former is engaged merely to practise medicine and surgery on soldiers under conditions of personal strain and danger, instead of on civilians under the ordinary conditions of civil life. But a little reflection will make it obvious that this and many other duties relating to the entire charge of soldiers and their equipment when *hors de combat* must be undertaken by the medical officers or not at all. It would be impossible to have a double staff of officers without greatly increasing expense, overlapping of energy, and division of authority. This system was tried under the old Medical Staff Corps and broke down egregiously. The present difficulty no doubt largely arises from the unprecedented necessity for extemporising a large number of military medical officers, who being unacquainted with all the details of medical military administration, as distinguished from professional services, can hardly do otherwise than interpret the former part of their duties without adequate data for sound judgment.

SOLDIERS' FOOD.

An Army Order issued on May 14th states that in order to make further provision for varying the dietary of units at the discretion of their commanding officers, it has been decided that from May 22nd an additional cash allowance of 1½*d.* per diem will be issued in lieu of ¼ lb. of bread, 1 oz. of cheese, and 1 oz. of jam now drawn by troops at home.

The modified field service scale of rations issuable at home in kind will be as follows:—

1 lb. fresh meat or 1 lb. preserved meat.
1 lb. bread or ¾ lb. biscuit or 1 lb flour.
2 oz. bacon.
½ oz. tea.
2 oz. sugar.
½ oz. salt.
1-20 oz. mustard.
1-36 oz. pepper.

When this ration is drawn a cash allowance of 5½*d.* a day will be issuable. It will be drawn by the officer commanding on the basis of the number of rations drawn in kind, and will be expended by him solely on messing.

In regard to this order it is well known that it is an erroneous policy to furnish too cheap or monotonous a diet, because its adoption tends to encourage disease and render the men unfit. It is to be hoped that the opportunity of varying the diet, furnished by this money allowance, will help to make the food more interesting, a matter of some physiological importance. It should also enable the substitution to be made of articles of equal nutrient value, as for example eggs for cheese, or peas and beans for cereals.

MILITARY MEDICAL OFFICERS AND CONTRIBUTIONS TO MEDICAL JOURNALS.

A large number of military medical officers do not seem to be aware that the King's Regulations prohibit the sending direct to medical journals of articles intended for publication. The War Office has hitherto been lenient in allowing us to submit such articles for approval before publication, but we have been requested to state that Paragraph 453 of the King's Regulations and Orders for the Army requires that such articles should be transmitted through the officer's commanding officer to the War Office, with a request that, if approved, it be forwarded by the War Office to the journal. This regulation applies not only to regular officers but to temporary officers, officers of the Special Reserve and of the Territorial Forces, and it includes all professional communications and case reports from military hospitals or affecting soldiers, as well as accounts of military organisations, hospitals or movements. The Regulation reads as follows:—

> 453. An officer or soldier is forbidden to publish in any form whatever, or communicate, either directly or indirectly, to the press, any military information, or his views on any military subject, without special authority; and an officer or soldier will be held responsible for all statements contained in communications to his friends which may subsequently be published in the press or otherwise. He is not to prejudge questions which are under the consideration of superior

military authority by the publication, anonymously or otherwise, of his opinions, and he is not to take part, in public, in a discussion relating to orders, regulations, or instructions issued by his superiors.

Any information of a professional nature which he may acquire while travelling or employed on duty is to be regarded as the property of the War Department, and is not to be published in any form without the previous sanction of the Army Council, or in India of the Commander-in-Chief.

When application is made for permission to publish any article, &c., the document will be either typewritten or in proof form, and will be submitted in duplicate direct to the War Office (or in India to the Commander-in-Chief). A statement will be enclosed from the authority (if any) under whom the applicant is immediately serving that such authority has no objection to permission being applied for. One of the copies will be retained at the War Office or by the Commander-in-Chief in India, as the case may be, for reference. Permission to publish will apply only to the article, &c., as submitted, and no alterations therein, except of a purely editorial nature, and no additions thereto are to be made subsequently without the authority of the Army Council (or in India of the Commander-in-Chief).

It is added that permission to publish the article will not convey official endorsement of its contents, and that no statement tending to imply official approval or endorsement is to be included in any part of the publication.

British Red Cross and the Order of St. John.—The work that is now being done by these combined organisations is truly enormous. The Hon. Arthur Stanley, M.V.O., M.P., the chairman of the Joint War Committee, writes to the *Times* that not only in France and Belgium are continuously increasing demands making themselves felt, but they have also had to follow the progress of our troops and those of the Allies abroad, so that Malta, Egypt, the Dardanelles, East Africa, Rhodesia, Serbia, and Montenegro are among the countries that look to it for help in addition to the 900 hospitals at home to which it supplies stores, motor ambulances, &c. The ever-increasing activities entail a constantly increasing expenditure, which amounts at the present to about £3000 a day.

Lord Lansdowne has been elected chairman of the British Red Cross in the room of the late Lord Rothschild.

The Zeppelin Threat: Surgical First Aid for the Metropolis.—London passed recently into and out of a Zeppelin scare, and it seems to us that the insouciance of the moment is almost as inexplicable as the panic which preceded it. Germany possesses Zeppelins, it is proved that they can easily reach London, and we know that the Germans would love to learn of their arrival. On the other hand, the metropolis is believed to be as adequately armed as possible against aerial attack. But supposing a raid should occur, it is well that it should be widely known that the medical profession has made certain preparations that are sure to be very useful. Existing organisations, it was felt, might not be able adequately to cope with a sudden demand for first aid to a large number of injured civilians, and in order to meet such an emergency the following steps have been recommended and adopted by the Royal Society of Medicine: To ascertain what hospitals, infirmaries, and dispensaries could do in the event of civilians being injured in their neighbourhood, firstly, in the matter of provision for first aid, how many individuals they could receive and treat, then to be transferred as quickly as possible to their homes, to hospitals, or to nursing homes; and secondly, how many they could receive for complete treatment. A map of the London area has been prepared and marked, showing these receiving centres with the number of cases receivable. If the map revealed that any district had no receiving centre, say within a radius of one mile, application was made to the local authorities inviting them to provide some suitable place—a town hall, a public bath, a library, or a school—to which the police and helpers might be directed to convey the injured. The local authorities would provide an adequate supply of the material required for first aid, and the committee have drawn up a list of such material with prices, and have arranged with some surgical supply company to provide at cost price. Emergency centres have been marked on the map, and copies of the map or full topographical particulars have been sent to every police office. If police offices are not already supplied with a map showing the position of every ambulance, whether County Council, St. John, or Bischoffsheim, such maps can be supplied. A list of surgeons, general practitioners, and district nurses willing to help in each district has been prepared, with names and full addresses, and (when possible) telephone numbers, and a copy of each district list has been sent to each police office in the district.

The scheme, we are informed by Mr. J. Y. W. MacAlister, upon whom the organisation has devolved, originated in a suggestion made by Dr. H. Moreland McCrea, and a similar scheme has been organised for the East Coast with the coöperation of the War Office.

Vacancies for Medical Officers.—We are informed that there are still a few vacancies for medical men wishing to take commissions in the 1st London (City of London) Sanitary Company. The duties of this company consist in organising and supervising the sanitary work of the army at the front and at home. It is desirable, therefore, that medical men applying for commissions in this company should have a knowledge of sanitation. The posts are especially suitable for men in the public health or education service, who can be released by their councils for military work. Those joining at once may expect to be ordered abroad at an early date. Applications for commissions should be made to the Officer Commanding, 1st London (City of London) Sanitary Company, Room B.6, Duke of York's Headquarters, Chelsea, London, S.W.

Behind the Battle Lines in France.—A report has been issued on three months' work carried on by the War Victims' Relief Committee of the Society of Friends. In response to an appeal from the Prefect of the Marne the Society of Friends undertook the administration of a maternity hospital at Châlons, a town famed in history as the site of the great battle in which Attila and his Huns were defeated by the Romans in 451. The hospital has been established on the initiative of Dr. Hilda Clark in a pavilion of the Asile des Vieillards et Hospice de Mendicité, an institution for homeless old people of the department. After necessary alterations had been made and much cleaning done it was opened on Dec. 6th. On the first floor are two long wards containing 28 beds in all, with a small ward partitioned off it. Below on the ground floor is the crèche to which older children may be brought. Here within sound of the guns, but in peace and comfort, the mothers rest, and here their babies are born. This maternity home is for those whose homes have been destroyed, the majority being refugees from the Ardennes or from Rheims and the occupied portion of the Marne. The total number of babies born was 63; no illness had occurred attributable to the confinement. Excellent work in various ways is carried on from this centre. An out-patients' department has been opened. Wooden huts have been built and roofless cottages repaired for those who have had their homes ruined. It is intended to render relief by the distribution of seeds, so that some at least of the vegetables upon which the people depend so largely for food will be available. The members of the expedition numbered originally 32, half of whom were doctors and nurses. Since leaving England at the beginning of November the numbers have been increased to some 70 workers, by whom much is being done to help the civil population who have suffered so cruelly from the effects of the war. The relations with the French military doctors have been most pleasant, and every assistance has been given by the officials, who fully appreciate these practical expressions of sympathy.

The Voluntary Aid Detachments.—The Voluntary Aid Detachments are sending volunteers to fill the ranks of nurses in the army, and numerous applicants have been critically interviewed by a Standing Committee at Devonshire House. The members of these detachments must have leave to apply from their commandant and county director. They must hold first aid and home nursing certificates, wear the regulation uniform, live under military discipline, and be inoculated against typhoid fever. After a month's probation they are called upon to sign for one year or the duration of the war. A salary of £20 a year is offered, and travelling, board, lodging, and washing expenses are paid, an allowance being made also of £1 per quarter for maintenance of the uniform.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—A Comitia was held on May 13th, Dr. Frederick Taylor, the President, being in the chair. The following Members, who were elected to the Fellowship at the last meeting, were admitted as Fellows of the College: Dr. Archibald Donald, Dr. George Gavin Morrice, Dr. Thomas Beattie, Dr. Noel Dean Bardswell, Dr. Frank Cecil Eve, Dr. John Hay, Dr. George William Watson, Dr. Reginald Charles Jewesbury, Dr. Edwin Greaves Fearnsides, Dr. John George Adami, and Dr. Grafton Elliot Smith. There being no further business the President dissolved the Comitia.

ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At a meeting of the Comitia of the Royal College of Physicians of London on April 29th, and of the Council of the Royal College of Surgeons on May 13th, diplomas of L.R.C.P. and M.R.C.S. were respectively conferred upon 103 candidates (including two ladies) who have passed the Final Examination of the Conjoint Board in Medicine, Surgery, and Midwifery, and have complied with the by-laws. The following are the names and medical schools of the successful candidates:—

Alan Colpitts Ainsley, B.A. Cantab., Cambridge University and London Hospital; William Guy Embleton Allen, St. Bartholomew's Hospital; David William Jabez Andrews, Middlesex Hospital; Frank Longstaff Apperly, B.A. Oxon, Oxford and Dublin Universities; Joseph Herbert Bayley, London Hospital; William Kenneth Bigger, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Cyril Mary Brophy, University College Hospital; Johannes Karel Joseph Chambry, Amsterdam and St. Mary's Hospital; Francis Bernard Chavasse, B A. Oxon., Oxford and Liverpool Universities; Percival Cheal, London Hospital; Ying-Jue Cieh, King's College and St. Thomas's Hospital; Eric Clarence Cline, Guy's Hospital; Hugh Michael Collins, Madras and London Hospital; Wilfred Leigh Cox, Middlesex Hospital; Reginald Curle, Guy's Hospital; Edmund Sheppard Cuthbert, St. Bartholomew's Hospital; Ernest Ivon Davies, Cardiff and Charing Cross Hospital; John Kenyon Davies Cardiff and St. Bartholomew's Hospital; Wilfred Angel Easton and Cyril Henry Edwards, L.D.S. Eng., Guy's Hospital; Moustafa Fahmy, Cairo and London Hospital; Nashed Fahmy, Cairo and King's College Hospital; Israel Feldman, jun., and Israel Feldman, sen., London Hospital; Francis John Folinsbee, M.D. West. Univ., Western University; Annie Mary Cecilia Forster, Royal Free Hospital; Harold Gardiner-Hill, B.A. Cantab., Cambridge University and St. Thomas's Hospital; George Cowley Gell, L D.S. Eng., Middlesex Hospital; Colin Charles Gordon Gibson, Guy's Hospital; Bernard Heynes Greensill, Birmingham University; John Richard Griffith, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Harold Stanley Groves, Guy's Hospital; William Tudor Gwynne-Jones, London Hospital; George Habgood, B.A. Cantab., Cambridge University and London Hospital; Stanley Allman Hall, Middlesex Hospital; Robert Hargreaves, B A. Cantab., Cambridge University and University College Hospital; Cyril Edward Harrison, Middlesex Hospital; Henry Saumarez Hensman, Madras and London Hospital; Rupert Conrad Hewitt, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Wallace Hillbrook, B.A. Cantab., Cambridge University and St. George's Hospital; Richard Annesley Holmes, L.M.S.S.A. Lond., Guy's Hospital; Rhys Bevan John, B.A. Oxon., Oxford University and Westminster Hospital; David Rees Jones and Nicholas Edward Kendall, Guy's Hospital; John Scott Kennedy, Cambridge University and St. George's Hospital; Hugh James McCurrich, Bristol University and St. Bartholomew's Hospital; *Alexander Joseph Victor McDonnell, London Hospital; Archibald McInnis, M.B. Toronto, Toronto University and London Hospital; Samuel Mallinick, Halle and London Hospital; Ganapathy Mallya, Madras and St. Bartholomew's Hospital; Alwyne Harold Manfield, London Hospital; Charles Jennings Marshall, M.D., B.S. Lond., Charing Cross Hospital; Robert Paul Scott Mason, Middlesex Hospital; Bireswar Mitra, L.M.S. Calcutta, Calcutta Medical College and Guy's Hospital; Cotton Grimley Tenison Mosse, B.A. Cantab., Cambridge University and London Hospital; Newman Frederick Norman, St. Bartholomew's Hospital; Duncan Collingwood Ogilvie, Middlesex Hospital; Thomas Owen, Cambridge University and St. Bartholomew's Hospital; Cuthbert Felix Oliver Pandithesekere, Ceylon Medical College and University College Hospital; Owen Parry-Jones, London Hospital; Edward Crosby Peers, Guy's Hospital; Walter Spencer Johannes Peiris, Ceylon Medical College and London Hospital; Lloyd Desbat Phillips, University College Hospital; Harold Dobson Pickles, Leeds University; Stanley Victor Percy Pill, St. Mary's Hospital; Raymond Fearle Pinson, Birmingham University; Garnet Wolseley Pool and Charles Leslie Grove Powell, St. Thomas's Hospital; John Wootton Rammell, London Hospital; Douglas Oliver Richards, Guy's Hospital; Arthur Eaton Richmond, St. Thomas's Hospital; Alexander Iskander Rihan, Constantinople and St. Bartholomew's Hospital; Gordon Wilfrid Richard Rudkin, University College Hospital; Basil Sampson, Guy's Hospital; *Saroz Kumar Sanyal, London Hospital; Charles Harley Savory, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Ellis Herbert Sydney Scarr, Manchester University; John Godfrey Bradley Smith, St. Bartholomew's Hospital; John Aubrey Brooking Snell, B A. Cantab., Cambridge University and University College Hospital; Theodore Howard Somervell, B.A. Cantab., Cambridge University and University College Hospital; Hugh Gordon Sparrow, St. George's Hospital and Durham University; George Sydney Stathers, Cambridge University and St. Bartholomew's Hospital; Robert Gee Sterling, London Hospital; David Page Thomas, St. Bartholomew's Hospital; Donald Carmichael Thomas, St. Thomas's Hospital Rufus Clifford Thomas, Westminster Hospital; Humphrey Quentin Forsyth Thompson, Guy's Hospital; Ralph Reakes Thompson, London Hospital; Joseph Russell Tibbles, Aberdeen University and London Hospital; Edgar James Tyrrell, M.B., B.S.Durh., Durham University; John Ernest Alfred Underwood, B.Sc. Lond., University College Hospital; Shankarlal Kunvarji Vaidya, L.M.S. Bombay, Bombay University and London Hospital; William Ernest Wade, Cardiff and Charing Cross Hospital; Percy Wallice, Cambridge University and London Hospital; Karl Johan Fredrik Westman, Guy's Hospital; Edward Scott White, B.Sc. Bristol, Bristol University; Eva Muriel White, Royal Free Hospital; Hugh Anthony Bulstrode Whitelocke, B.A. Oxon., Oxford University and King's College Hospital; John Douglas Wilkinson, St. Thomas's Hospital; Cyril Mathias Williams, Cardiff and St. Mary's Hospital; Gerald Richard Courtenay Wilson, St. Thomas's Hospital; William Bernard Wilson, St. Bartholomew's Hospital; and Guy Walker Woodhouse, B.A. Cantab., Cambridge University and St. Thomas's Hospital.

* Both diplomas conferred on May 13th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An ordinary meeting of the Council was held on May 13th, Sir Watson Cheyne, the President, being in the chair. Mr. Frederick George Larkin was introduced, and after signing the by-laws and making the required declaration was admitted a Fellow of the College. Mr. J. Hutchinson was introduced, and the President handed to him the Jacksonian prize for the year 1914, together with a document declaratory of the award. Mr. J. F. Colyer was introduced, and the President handed to him the John Tomes prize for 1912–14, together with a document declaratory of the award. It was resolved to issue diplomas of Membership to 103 successful candidates. The secretary reported the delivery of three demonstrations in the Museum by Mr. Shattock, the pathological curator.—At the Primary Fellowship Examination in Anatomy and Physiology held on May 5th, 6th, 10th, and 11th, 42 candidates presented themselves, of whom 33 per cent. were approved and 67 per cent. were rejected. The following are the names and schools of the successful candidates:—

Gustave Adler, London Hospital; Reginald Harold Bridge, M.B., Ch.M. Sydney, Sydney University and Middlesex Hospital; William Bashall Gabriel, Middlesex Hospital; David John Harries, M.D., B.S., B.Sc. Lond., L.R.C.P., M.R.C.S., Cardiff and University College Hospital; Jack Joffe, Guy's Hospital; John Isaie Kühne, King's College; Charles Jennings Marshall, M.D., B.S. Lond., L.R.C.P., M.R.C.S., Cardiff and Charing Cross Hospital; Francis Courtenay Mason, Middlesex Hospital; Arthur Morford, B.Sc. Lond., St. Bartholomew's Hospital; John William Glanmor Phillips, St. Mary's Hospital; Raghunath Dadoba Shirwalkar, B.A. Bombay, Bombay University and University College Hospital; Gilbert Innes Strachan, M.D. Glasg., Glasgow University and Middlesex Hospital; Charles Maitland Titterton, St. Bartholomew's Hospital; and David Percival Dalbreck Wilkie, M.D., Ch.B. Edin., Edinburgh University.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN: SCHOLARSHIP GIVEN BY HER MAJESTY THE QUEEN.—The Queen has given the sum of £250 to pay for the training and expenses of a student at the London (Royal Free Hospital) School of Medicine for Women for a five years' course. The money is part of a gift to the Queen from the wives of Freemasons to help members of the professional classes who may be in difficulties owing to the war. The council of the London (Royal Free Hospital) School of Medicine for Women will award the scholarship in July, 1915, to a student who intends to begin a course of study in the October following. The scholarship will be of the value of £50 a year for five years, subject to the student pursuing her course to the satisfaction of the council. Candidates must have passed a preliminary arts examination recognised for purposes of registration by the General Medical Council, or the London Matriculation, or an examination which gives exemption from it. Forms of application can be obtained from the secretary of the school, and must be returned filled in not later than June 24th, 1915, accompanied by two testimonials, one of which must be from a previous teacher, and by a statement of financial circumstances with special reference to difficulties due to the war. Selected candidates will be interviewed, and a medical certificate of sound health may be required. In the event of the council deeming it necessary, an examination will be held consisting of a general knowledge paper and an essay.

UNIVERSITY OF LONDON, UNIVERSITY COLLEGE.—A new edition of the University College, London, "Pro Patria" is in course of preparation, and will be issued shortly. Past and present students, or their relatives and friends on their behalf, are invited to send full particulars of the capacity in which they are serving the country at the present time. Particulars of rank, ship, and regiment should be addressed to the Publications Secretary, University College, London (Gower-street, W.C.).

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Reconstruction of the Government.

ON Wednesday, May 19th, Mr. ASQUITH announced that steps were in contemplation involving the reconstruction of the Government on a broader political basis.

The Whitsuntide Holidays.

On the same evening both Houses agreed to adjourn for the Whitsuntide holidays until June 3rd.

Immature Spirits and the Preparation of Medicines.

Several times the attention of the Government was drawn during the past week to apprehensions that the compulsory bonding of immature spirits under the Immature Spirits Bill would interfere with the manufacture and use of medicinal preparations in which spirits played a part. Assurances have been given, and amendments introduced into the Bill, for the purpose of making clear that there is no intention that any such interference will take place.

In committee on the Bill in the House of Commons on Monday, May 17th, Mr. GLYN-JONES pointed out that as he read the Bill, laudanum and other tinctures were definitely included in the provision that no immature spirits should be delivered for home consumption. It was true that immature spirits could be by a specified exception supplied to manufacturing chemists for the manufacture of laudanum, but under the Bill they could not deliver it for home consumption for three years.

Sir JOHN SIMON, the Attorney-General, said that the honourable Member feared that the withdrawal of spirits by manufacturing chemists would mean that some heavy duty would be imposed on the spirits that were used in making such things as laudanum. The honourable Member had already the assurance of the Chancellor of the Exchequer that that was not so and an assurance from him also. He again said that it was not so. When the House came to consider the question of the taxes on spirits, the honourable Member would find that there was nothing whatever in the proposals of the Government which would put the manufacturing chemist at a disadvantage as compared with what he was before. The clause did not affect in the least the sale of laudanum by anyone authorised to sell it. The only time when the clause of the Bill would operate was when spirits passed out of a bonded warehouse. Inasmuch as no manufacturing chemist ever made laudanum in bond, he would use the spirit after it had been taken out of bond.

At a later stage, on the motion of Sir JOHN SIMON, an amendment was inserted in the Bill laying down that the restriction against the removal of immature spirits from bond should not apply to spirits delivered for purposes for which they might for the time being be delivered free from all duty "or mixtures, compounds, or preparations in respect of the spirit contained in them or used in their preparation or manufacture."

Mr. GLYN-JONES, commenting on this amendment, said that with words inserted there would be no difficulty about any duty on such a compound as landanum or other like compounds, and so far as he was concerned about this particular point he had been met. How much further the words went he was not in a position to say.

On Tuesday, May 18th, the Bill was considered on report.

Mr. GLYN-JONES moved to add to Clause 1 the following provision:—

> "Nothing contained in this section shall interfere with the supply of rectified spirits of wine for the purpose of making medicines to registered medical practitioners, hospitals, and to persons, firms, and bodies corporate entitled to carry on the business of chemists and druggists."

The honourable Member said that he had received communications from the Pharmaceutical Society of Great Britain and also from the General Medical Council requesting that this alteration should be made in the Bill. They as experts were satisfied that the Bill as it stood seriously interfered with obtaining rectified spirits of wine for the purpose of making medicine. The Pharmaceutical Society had forwarded to him a copy of a letter which it had sent to the Chancellor of the Exchequer. In it it was stated that out of 427 preparations in the Pharmacopœia, in 263 rectified spirits of wine formed a necessary ingredient. As the law now stood it was illegal for anyone to make these preparations without rectified spirits of wine. Out of 20,000 physicians' prescriptions examined 2521 contained Pharmacopœia ingredients made with rectified spirits, and in 343 rectified spirits of wine were actually ordered as a separate ingredient. The British Medical Association had also sent a letter to the Chancellor of the Exchequer saying that they viewed with great concern the provisions of the Bill, inasmuch as it would be impossible for medical men who dispense their own medicines, and also for pharmacists who dispense medicines, to obtain rectified spirits of wine under the Bill as it stood.

Mr. LLOYD GEORGE accepted the provision proposed by Mr. GLYN-JONES. It was embodied in the Bill.

The Bill was afterwards read a third time.

Mental Treatment Bill.

This Bill has been dropped.

HOUSE OF COMMONS.

WEDNESDAY, MAY 12TH.

Motor Ambulances at the Front.

Sir GEORGE SCOTT ROBERTSON asked the Under Secretary for War whether there was a deficiency in motor ambulances for the carrying of British wounded from the front to the hospitals; whether this deficiency was particularly noticeable after the recent fighting at Neuve Chapelle; whether he was aware that charitable organisations anticipated no difficulty in purchasing such ambulances from the manufacturers provided sufficient funds could be collected; and, supposing the facts were as alleged, would he say why the Government failed to provide sufficient mechanical transport for the service of its wounded soldiers.—Mr. TENNANT replied: No, sir, there is no such deficiency, nor is there any truth that it was particularly noticeable after the recent fighting at Neuve Chapelle. On the contrary, I am informed that the work of the motor ambulance convoys throughout the battle was deserving of special praise.

Sir GEORGE SCOTT ROBERTSON: Is it not a fact that the Red Cross Association has made the allegations referred to in the question and has asked for further motor ambulances?—Mr. TENNANT: I have no knowledge of any such allegation being made by the Red Cross Association, and I should be very much surprised if they have made it.

Medical Men in the Ardee Union.

Mr. PATRICK WHITE asked the Chief Secretary to the Lord Lieutenant of Ireland whether, having regard to the prolonged controversy which had existed between the elected representatives of the people of the Ardee union and the Local Government Board regarding the appointment of local doctors and the area of their duties, and to the fact that numerous complaints had been made that the arrangements made by the Local Government Board had worked injuriously to the sick poor, he would appoint a small committee to inquire into the matter and report on it.—Mr. BIRRELL answered: The present medical relief arrangements in the Ardee union have been in operation for the past ten years and are satisfactory as regards the provision made for the medical care and treatment of the sick poor. Ardee union is more favourably circumstanced as regards the number of dispensary doctors employed than most unions in Ireland, and there is no necessity whatever for reopening this question. At the present time, when it is difficult to obtain medical officers for existing dispensaries, the creation of a new office is highly undesirable.

Isolation Hospitals at Hull.

Replying to Mr. GEORGE ROBERTS, Mr. HERBERT SAMUEL (President of the Local Government Board) wrote: I am informed that the following cases were under treatment in the isolation hospitals of the corporation of Kingston-upon-Hull on the 6th inst.:—City Hospital, Hedon-road: measles, 2; scarlet fever, 56; diphtheria, 58; tuberculosis, 22; German measles, 8; German measles and acute rheumatism, 1; German measles and scarlet fever, 1; sent in for typhoid but proved to be scarlet fever, 1; sent in for typhoid but proved to be pneumonia, 1. Evan Fraser Hospital, Sutton: measles, 1; scarlet fever, 47; and diphtheria, 1.

Vaccination against Cerebro-Spinal Meningitis.

Mr. SUTTON asked the President of the Local Government Board whether he was aware that the medical officer of Salisbury had issued a notice to householders advising vaccination against cerebro-spinal meningitis; what was the nature and substance of the vaccine used for the purpose; and could he say how many of the inhabitants of Salisbury had been inoculated at the public expense.—Mr. HERBERT SAMUEL wrote in reply: The answer to the first part of the question is in the affirmative. The vaccine used contains dead meningococci, and was prepared and standardised by the Lister Institute. Approximately 2600 of the inhabitants have been inoculated at the public expense.

THURSDAY, MAY 13TH.

The Mental Treatment Bill.

Mr. RENDALL asked the Under Secretary for War what arrangements had been made by the War Office to provide hospital treatment on purely medical lines for cases of nerve strain among the rank and file where each case might be sifted and diagnosed on arrival in England before being placed in charge of medical officers (Royal Army Medical Corps) who had been taken over from the asylum service.—

Mr. TENNANT said in reply: At large hospital centres in France specialists in nervous diseases not alienists, see all cases of nerve strain and determine to which clearing hospital the cases should be sent on arrival in England. At these hospitals the cases are carefully gone into, and those who are suitable are transferred to certain special hospitals which are quite distinct from what my honourable friend calls the asylum service.

Mr. RENDALL: Will the soldiers who are placed in such hospitals, which are really asylums, have the same right of appeal against decisions as ordinary civilians?—Mr. TENNANT: I do not quite understand the question. Perhaps my honourable friend will put a fresh question.

Mr. RENDALL asked the right honourable gentleman whether he would consider the advisability of providing for the treatment of transiently acute cases of mental disturbance among soldiers by the methods applicable to delirious (toxic) cases in general hospitals, with a view to keeping them apart from lunacy and asylum management.—Mr. TENNANT answered: The cases mentioned in the question are dealt with at either "D" Block, Netley, or Napsbury Military Hospital. These cases are kept absolutely apart from the certified mental cases and the hospitals are under War Office management.

Mr. RENDALL asked the Under Secretary for the Home Department whether he was aware that by the provisions of the Mental Treatment Bill now before the House the soldier disabled by nerve-strain would be liable, when discharged uncured from the army, to be placed, at the discretion of one doctor, for six months under care and treatment in an institution intended for the insane; that there was no provision in the Bill for any appeal to a magistrate; and would he undertake to propose or accept an amendment whereby the ordinary safeguards extended hitherto to all British subjects protecting them from unjust treatment might be made equally applicable for the protection of soldiers.—Mr. CECIL HARMSWORTH replied: I think that my honourable friend has misunderstood the object of the Bill, which was to secure suitable treatment of cases of nerve-strain without compulsory detention, but I need not go further into the matter, as I hope that arrangements for this purpose may now be made without legislation and that it will not be necessary to proceed with the Bill.

Vaccination in Ireland.

Mr. PATRICK WHITE asked the Chief Secretary to the Lord Lieutenant of Ireland, whether the same facilities existed in Ireland as in England to enable conscientious objectors to have their children exempted from vaccination; and, if not, whether, having regard to the growing demand for exemption in Ireland, he would take steps to introduce legislation assimilating the law in the two countries.—Mr. BIRRELL replied: The answer to the first part of the question is in the negative. I am not aware of any general demand for a change in the existing law as regards Ireland, and I do not consider the present a suitable opportunity for legislation on this subject.

Transmission of Disease by Flies.

Mr. BOLAND asked the President of the Local Government Board what steps, if any, had been taken to inform the public as to the danger to health involved in the transmission of disease by flies under existing war conditions; whether any leaflets had been published on the subject, and, if not, whether the leaflet published by the Zoological Society of London would be utilised; and whether steps would be taken to set up a small committee to deal with the subject.—Mr. HERBERT SAMUEL answered: The Board have issued seven reports on "Flies as Carriers of Infection," and they have during the last few years warned local authorities by circular at the beginning of summer of the dangers of allowing accumulations of refuse, which may form breeding grounds for flies, to remain in the neighbourhood of dwellings. They had for some time past been urging individual local authorities who are not dealing satisfactorily with the refuse of their districts, to improve their methods. In a circular letter which is about to be issued, attention will again be drawn to the matter. The War Office and my department are coöperating in this as in other matters affecting the health of the troops and of the civil population. A number of local authorities have issued posters and leaflets on the subject. I am considering the preparation and issue by the Local Government Board of a series of model leaflets on this and other health subjects, which local authorities could use if they so desired.

Lord ROBERT CECIL: Can the right honourable gentleman say whether any communication has taken place between the English and French authorities upon this point?—Mr. HERBERT SAMUEL: Not so far as I am aware.

Cardiff Mental Hospital and the War Office.

Mr. TYSON WILSON asked the Under Secretary for War whether the Cardiff Mental Hospital had been taken over by the War Office for the accommodation of wounded soldiers; and, if so, whether he could say where the patients that were being treated in the hospital had been transferred; and whether arrangements had been made for their relatives to visit them.—Mr. TENNANT furnished the following written answer: The Cardiff Mental Hospital is being taken over. The patients have been removed under arrangements initiated by the Board of Control with the approval of the Home Secretary to the following asylums: Gloucester, Hereford, Monmouth, Newport, Glamorgan, Carmarthen, Brecon, and Radnor. In reply to the last part of the question, the relatives will, of course, have facilities for visiting.

Schools for Mothers.

In the course of the debate on the Education Estimates Mr. J. A. PEASE (President of the Board of Education) made reference to the work that was being done by schools for mothers. Nothing was more important in regard to the prevention of infantile mortality and the preservation of the health of small children than that the mothers should be educated how to rear them. Recently the Local Government Board had been enabled to help forward this work by grants for maternity and child welfare. The Board of Education had been helping something like 151 schools for mothers. In order to prevent overlapping it had been decided that all matters connected with institutions provided by sanitary authorities, as well as matters connected with voluntary infant consultation, should be supported out of grants by the Local Government Board. All matters connected with schools, as defined by the regulations of the Board of Education, should be in the province of the Board of Education. In that way he believed a satisfactory working arrangement would be arrived at which would secure not only a proper bringing up of the children but due attention to health. The great object was to get the children to the schools in a healthy condition. If that was achieved, the children would learn a great deal more, and there would be much less waste of public money than there had been in the past. The demand for women in many directions had produced also a demand for women who had babies or very small children in their homes. One of the great social dangers in the country had been that these children were not properly provided for when their mothers were at work. By a system of crèches which had been supported by the Board of Education and by grants very good work was being done. There were now 77 institutions of this kind in the country. He did not think that the value of that kind of work could be overrated.

Finances of Universities.

Mr. PEASE in a subsequent part of his speech referred to the loss of fees which universities had experienced through the withdrawal of students for war service. Consideration, he said, was being given by a departmental committee which would report to the Treasury on the advisability of enabling the provincial universities other than Oxford and Cambridge to tide over the financial position into which the war had thrown them. He had not much to say with regard to Wales, but in connexion with university work there it was noteworthy that all parties concerned were united in a real endeavour to organise their university education and were now considering the whole matter. In the past months a departmental committee had been sitting to consider the best means of founding a Welsh medical school at Cardiff.

TUESDAY, MAY 18TH.

The Notification of Births Act.

Lord ROBERT CECIL asked the President of the Local Government Board whether, having regard to the importance, especially at the present time, of taking steps to reduce infant mortality, he would consider the desirability of amending the Notification of Births Act so as to confer an express power on local authorities to provide health visitors, maternity centres, and similar arrangements for promoting infant welfare.—Mr. HERBERT SAMUEL replied: There can be no division of opinion as to the great importance of measures for reducing infant mortality, and I may perhaps remind the noble lord that the Government have undertaken to make substantial grants in aid of maternity centres and other agencies for infant welfare, which are approved by the Local Government Board. It would, I think, be an advantage if the Notification of Births Act were amended in the way suggested in the question. Notifications are of little value unless they are followed up by health visiting and by the provision of advice and skilled assistance to mothers. The Act itself confers on local authorities no express power to do this work, and at present recourse has to be had to powers in other Acts which were not framed with infant welfare particularly in view. One result is that the powers of a county council adopting the Act differ from those of a district council. If it were shown that a small amending Bill such as is suggested would meet with general support, I should be glad to consider the early introduction of such a measure.

Rating of Houses used as Hospitals.

Mr. WHELER asked the President of the Local Government Board whether his attention had been called to the fact that many private houses now being used as hospitals for the wounded in the war were liable to be rated; and whether he would consider introducing a Bill to enable their exemption from rates where the guardians were satisfied that such houses were *bonâ fide* used solely for such purpose and that only those wounded and those necessarily attendant on them resided therein.—Mr. HERBERT SAMUEL said in reply: If a local authority, in cases of the kind referred to, should see fit to exempt the premises from rating, the Board would not in the present circumstances wish to take exception to such a course.

Medical Officers in Scotland and the War.

Mr. GINNELL asked the Secretary for Scotland to state the number of medical officers of local administrative bodies in Scotland who had volunteered for service in the present war; the number of them serving; and the treatment of them by those bodies generally in regard to continuance of salary, payment of substitute, and keeping their positions vacant for them.—Mr. MCKINNON WOOD wrote in reply: I have no information as to the total number of medical officers of local authorities in Scotland who have volunteered for service. There are, so far as I am aware, 17 public health medical officers, 32 Poor-law medical officers, and 26 school medical officers (of whom some may also be health officers), who are or have been serving. I am informed that their posts are as a rule kept open for them. Health officers either receive full pay and nominate their own substitutes, or if the local authority makes arrangements for carrying on their work, receive full pay less military pay or a part thereof. In the case of the school medical officers, the local authorities have made arrangements to secure them against any financial loss. I have no information as to the financial arrangements in the case of Poor-law medical officers.

The Opium Conference.

Mr. THEODORE TAYLOR asked the Under Secretary of State for Foreign Affairs whether, with a view to restrict the use of morphia to medical and legitimate purposes, it was the intention of the British Government to sign the special protocol prepared as the result of the third Hague Opium Conference in June, 1914, which had already been signed by China, the United States, and the Netherlands.—Mr. PRIMROSE answered: A protocol has been opened at The Hague to receive the signatures of those Powers who intend to put the Opium Convention into force without waiting for the ratification by all the signatory Powers. I do not, however, consider it practicable in the existing circumstances to take any action at present beyond depositing the ratification of the signature of the British delegates, which has already been done. It has been the guiding principle of His Majesty's Government throughout the protracted negotiations that, though fully prepared to make all useful sacrifices in the interests of humanity, they could only secure the objects of the Convention—namely, the suppression of the illicit trade not only in morphia, but also in opium, cocaine, and other noxious drugs—by practically universal international coöperation. The attainment of those objects is not, in the opinion of His Majesty's Government, likely to be hastened by action on their part in the sense indicated by the honourable Member.

WEDNESDAY, MAY 19TH.

Medical Men and War Service.

Mr. JOYNSON-HICKS asked the Under Secretary for War whether he would give the number of doctors in the Royal Army Medical Corps on the active and Special Reserve lists at the present time; and what was the number in the Territorial Medical Corps.—Mr. TENNANT answered: The numbers are as follows:—

Army Medical Service and R.A.M.C.	1008
Re-employed retired R.A.M.C. officers	174
Special Reserve R.A.M.C. officers	623
Temporarily commissioned officers	3100
Territorial Force R.A.M.C.	2122
Total	7027

Mr. JOYNSON-HICKS asked the right honourable gentleman whether some 5000 medical men had volunteered their services during the war, and how many of these were now in actual service; and whether there was any scarcity of medical officers either at home or at the front.—Mr. TENNANT replied: More than 5000 medical men have offered their services, and 3100 have actually been appointed. This is in addition to officers of the Special Reserve. There is not at the moment any scarcity of medical officers either at home or at the front, but a further large number will be required.

Mr. JOYNSON-HICKS further asked the right honourable gentleman whether he could state the number of lieutenants, captains, majors, lieutenant-colonels, and colonels in the Royal Army Medical Corps on July 31st, 1914, and March 31st, 1915, and why there had been no promotions other than those arising in the ordinary course of service from the rank of captain to major.—Mr. TENNANT said in reply: The numbers are:—

	July 31st, 1914.	March 31st, 1915.
Colonels	29	99
Lieutenant-Colonels ...	128	225
Majors	341	185
Captains	379	477
Lieutenants	127	—
Total	1004	986

There have been 14 promotions from captain to major other than in the ordinary course of service.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BLANDY, LIZZIE, M.R.C.S., L.R.C.P. Edin., has been appointed House Surgeon to the Royal Free Hospital.

COX, W. J., M.B., Ch.B. Manch., has been appointed Acting Medical Officer of Health for Luton.

EADIE, W., M.B., Ch.B. Edin., has been appointed Medical Officer of Health and Medical Superintendant of the Fever Hospital, Workington.

HARRIS, DUDLEY RAYMOND, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the New Children's Scattered Home by the Falmouth Board of Guardians.

HUNTER, T. R., L.R.C.P. & S. Edin., L.F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Cardenden District of the county of Fife.

JOHNSTON, G. JAMESON, M.B., F.R.C.S. Irel., has been appointed Honorary Consulting Surgeon to the Royal Hospital for Incurables, Dublin.

JONES, BLACK, M.D. Lond., has been appointed Medical Officer of Health for Builth Wells.

MCDONALD, NIEL, M.B., Ch.B. Manch., has been appointed Resident Medical Officer at the Military Wing of the Royal Free Hospital.

NUNAN, T. J., L.R.C.P. & S. Irel., has been appointed Dispensary Medical Officer for Mountrath.

PIERSE, JOHN A., M.B., B.Ch.N.U.I., has been appointed House Surgeon to the Woolwich Infirmary.

PILLMAN, EMMA C., M.B., B.S., has been appointed House Physician to the Royal Free Hospital.

THOMPSON, J. A., L.R.C.P. & S. Irel., has been appointed Medical Officer for the Tempo Dispensary District by the Enniskillen Board of Guardians.

WELFORD, C. H., M.D. Aberd., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Staindrop District of the county of Durham.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

ALL SAINTS HOSPITAL FOR GENITO-URINARY DISEASES, Vauxhall Bridge-road, S.W.—House Surgeon for afternoon work only.

ALTON, HANTS. LORD MAYOR TRELOAR CRIPPLES' HOSPITAL.—Two Assistant Resident Medical Officers. Salary as arranged, with board, residence, and laundry.

BIRKENHEAD BOROUGH HOSPITAL.—Female Senior and Junior House Surgeons. Salary £180 and £150 per annum respectively, with board and laundry.

BIRMINGHAM GENERAL DISPENSARY.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, attendance, &c.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Senior House Surgeon. Salary £110 per annum, with board, residence, and attendance.

BOLTON INFIRMARY AND DISPENSARY.—Third House Surgeon. Salary £170 per annum, with apartments, board, and attendance.

BRADFORD CHILDREN'S HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.

BRIGHTON COUNTY BOROUGH ISOLATION HOSPITAL.—Resident Medical Officer. Salary £200 per annum, with board and lodging.

BRISTOL GENERAL HOSPITAL.—House Surgeon and Casualty House Surgeon, both for six months. Salary at rate of £150 per annum, with board, residence, &c.

BRISTOL ROYAL INFIRMARY.—Throat, Nose, and Ear House Surgeon for six months. Salary at rate of £120 per annum, with board, apartments, and laundry.

BURNLEY, VICTORIA HOSPITAL.—House Surgeon. Salary £135 per annum, with residence, board, and washing.

BURY INFIRMARY.—Senior and Junior House Surgeons. Salary £175 and £150 per annum respectively, with board, residence, and washing.

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Physician for six months. Salary £100 per annum, with apartments, board, and laundry.

CAMBRIDGE, ADDENBROOKE'S HOSPITAL.—Honorary Assistant Surgeon for Ear, Nose, and Throat Department. Also Honorary Assistant Surgeon for Ophthalmic Department.

CARDIFF, WELSH METROPOLITAN WAR HOSPITAL, Whitchurch, near Cardiff.—Junior Resident Surgeon. Salary at rate of £1 per day, with board, lodging, &c.

CARLISLE NON-PROVIDENT DISPENSARY.—Resident Medical Officer. Salary £200 per annum, with apartments (not board).

CARMARTHEN, JOINT COUNTIES ASYLUM.—Temporary Second Assistant Medical Officer. Salary at rate of £200 per annum, with board, lodging, washing, &c.

CITY OF LONDON LYING-IN HOSPITAL, City-road, E.C.—Resident Medical Officer for four months.

DUMFRIES, CRICHTON ROYAL.—Temporary Assistant Physician, unmarried. Salary at rate of 5 guineas a week, with apartments, board, laundry, and attendance.

EALING, BOROUGH OF.—Medical Officer of Health and School Medical Officer. Salary £700 per annum.

EDMONTON MILITARY HOSPITAL.—Assistant Surgeons and Physicians Salary £1 daily, with residence, board, and lodging.

EXETER, ROYAL DEVON AND EXETER HOSPITAL.—House Physician for six months. Salary at rate of £150 per annum, with board, apartments, and washing.

FOLKESTONE, ROYAL VICTORIA HOSPITAL.—House Surgeon. Salary as agreed, with board, residence, and laundry.

GLASGOW FEVER HOSPITALS.—Physician Superintendent. Salary £600 per annum, with free house.

GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL, OBSTETRICAL DEPARTMENT.—Two Indoor House Surgeons and Two Outdoor House Surgeons. Also One Female Outdoor House Surgeon at West End Branch. All for three months.

GRAVESEND HOSPITAL.—House Surgeon. Liberal salary, with board, residence, and washing.

GUILDFORD, ROYAL SURREY COUNTY HOSPITAL.—House Surgeon. Salary £150 per annum, with board, residence, and laundry.

HARROGATE INFIRMARY.—Resident House Surgeon. Salary £100 per annum.

HULL ROYAL INFIRMARY.—House Physician, unmarried. Salary £105 per annum, with board and apartments. Also Assistant House Surgeon. Salary at rate of £100 per annum, with board and lodging. Also Casualty House Surgeon. Salary at rate of £80, with board and lodging.

KING EDWARD VII. SANATORIUM, Midhurst, Sussex.—Second Assistant Medical Officer. Salary £150 per annum, with board, lodging, and attendance.

LANCASTER COUNTY ASYLUM.—Temporary Assistant Medical Officer. Salary 6 guineas per week, with board, &c.

LEEDS CITY.—Medical Assistant in Public Health Department. Salary £350 per annum.

LIVERPOOL, ROYAL SOUTHERN HOSPITAL.—Honorary Assistant Laryngologist for Ear, Nose, and Throat Department.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN.—Lecturer in Physics.

MANCHESTER, ANCOATS HOSPITAL.—Senior House Surgeon. Salary £100 per annum. Also House Physician. Salary £80 per annum.

MANCHESTER CHILDREN'S HOSPITAL, Pendlebury, Gartside-street.—Medical Officer for Out-patients' Department. Salary £180 per annum.

MANCHESTER NORTHERN HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL, Fitzroy-square, W.—House Surgeon. Salary £150 per annum. Also Honorary Anæsthetist.

NEWCASTLE-UPON-TYNE, POOR-LAW INSTITUTION AND INFIRMARY, Westgate-road.—Assistant Resident Medical Officer, unmarried. Salary at rate of £250 per annum, with apartments, rations, and washing.

NORTHUMBERLAND, CHILDREN'S SANATORIUM, Stannington.—Female Resident Medical Officer. Salary £200 per annum, with board and washing.

NOTTINGHAM CHILDREN'S HOSPITAL.—Female House Surgeon. Salary at rate of £150 per annum, with apartments, board, and washing.

PADDINGTON GREEN CHILDREN'S HOSPITAL, W.—Temporary Surgeon in Charge of Out-patients.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—House Surgeon. Salary £120 per annum, with board, residence, and washing.

PORTSMOUTH WORKHOUSE INFIRMARY, WORKHOUSE, AND CHILDREN'S HOME.—Female Second Assistant Medical Officer. Salary £150 per annum, with apartments, rations, &c.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—House Physician and House Surgeon for six months. Salary £100 per annum, with board, residence, and washing. Also Assistant Physician.

ROTHERHAM HOSPITAL.—Junior House Surgeon. Salary £125 per annum, with board, lodging, and washing.

ROYAL ARMY MEDICAL CORPS (TERRITORIALS), THIRD 1ST HOME COUNTIES FIELD AMBULANCE, FOREIGN SERVICE UNIT, Maidstone.—Medical Officers.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W.—Resident Medical Officer.

ST. MARY'S HOSPITAL FOR WOMEN AND CHILDREN, Plaistow, E.—Resident Medical Officer and Assistant Resident Medical Officer. Salary at rate of £110 and £90 per annum respectively, with board, residence, and laundry.

SALISBURY GENERAL INFIRMARY.—House Surgeon and Assistant House Surgeon, unmarried. Salary £150 and £100 per annum respectively, with apartments, board, lodging, and washing.

SCARBOROUGH BOROUGH.—Temporary Medical Officer of Health. Salary at rate of £400 per annum.

SERBIA, ROADSIDE DISPENSARIES.—Medical Women. Salary £40 for three months.

SHEFFIELD ROYAL INFIRMARY.—House Surgeon and Assistant House Physician. Salary £100 per annum, with board and residence.

SHEFFIELD, WHARNCLIFFE WAR HOSPITAL, Middlewood-road.—Resident Medical Officers.

SHREWSBURY, ROYAL SALOP INFIRMARY.—House Physician. Salary at rate of £110 per annum, with board and apartments.

SOUTHAMPTON, PARISH INFIRMARY, Shirley Warren.—Resident Assistant Medical Officer. Salary £200 per annum, with apartments, rations, washing, and attendance.

SOUTH SHIELDS, INGHAM INFIRMARY AND SOUTH SHIELDS AND WESTOE DISPENSARY.—Female House Surgeon. Salary £150 per annum, with residence, board, and washing.

STROUD GENERAL HOSPITAL.—House Surgeon. Salary £120 per annum, with board, lodging, and washing.

SWANSEA EDUCATION COMMITTEE.—Temporary Assistant School Medical Officer. Salary £300 per annum.

SWANSEA GENERAL AND EYE HOSPITAL.—House Physician. Salary £125 per annum, with board, apartments, and washing.

VENTNOR, ROYAL NATIONAL HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST ON THE SEPARATE PRINCIPLE.—Assistant Resident Medical Officer, unmarried. Salary £150 per annum, with board, lodging, &c.

WALSALL AND DISTRICT HOSPITAL.—Assistant House Surgeon and Anæsthetist. Salary £150 per annum, with board, residence, and laundry.

WARRINGTON INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.

WARRINGTON, LORD DERBY WAR HOSPITAL.—Resident Physician.

WEST BROMWICH AND DISTRICT HOSPITAL.—House Surgeon and Assistant House Surgeon, unmarried. Salary £150 and £120 per annum respectively, with residence, board, and laundry.

WEST HAM AND EASTERN GENERAL HOSPITAL.—Resident Medical Officer. Salary £160 per annum. Also House Physicians. Salary £120 and £100 per annum, with board, residence, and washing.

WEST HAM UNION.—Second Assistant Resident Medical Officer and Fourth Female Assistant Medical Officer at Infirmary, Whipps Cross-road, Leytonstone, N.E. Salary £250 and £160 per annum respectively. Also Deputy Resident Medical Officer at Sick Home, 95, Forest-lane, Forest Gate, E. Salary £250 per annum. Also Female Assistant Medical Officer at Workhouse, Union-road, Leytonstone, N.E. Salary £140 per annum. Each with usual residential allowances.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £150 per annum, with board, apartments, and washing.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Resident Medical Officer and House Surgeon for six months. Salary at rate of £150 per annum, with board, rooms, and laundry.

WORCESTER, CITY AND COUNTY BOROUGH OF.—Female Assistant Medical Officer. Salary £300 per annum.

WORCESTER GENERAL INFIRMARY.—Resident Medical Officer. Salary £150 per annum, with board, residence, and washing.

WREXHAM INFIRMARY.—Resident House Surgeon. Salary £125 per annum, with board, lodging, and washing.

YORK RETREAT.—Junior Assistant Medical Officer. Salary £200 to £225 per annum, with board, lodging, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Houghton-le-Spring, in the county of Durham; at Swords, in the county of Dublin; and at Earls Barton, in the county of Northampton.

Births, Marriages, and Deaths.

BIRTHS.

BAYNE.—On May 13th, at Hollingwood, Oldham, the wife of Arthur Munby Bayne, M.B., of a son.

CARNARVON BROWN.—On May 12th, at Egdean, Sevenoaks, the wife of A. Carvarvon Brown, M.R.C.S., late of India, of a son.

FOREMAN.—On May 16th, at White Hall, Stourwood-avenue, Bournemouth, the wife of Mr. J. E. Foreman, of a daughter.

KEELING.—On May 16th, at Market Bosworth, the wife of Hugh Nevill Keeling, M.R.C.S., L.R.C.P. Lond., of a son.

MARRIAGE.—On May 15th, at Harley-street, London, W., the wife of Herbert J. Marriage, M.B., B.S. Lond., F.R.C.S. Eng., of a son.

WOOLLEY.—On May 17th, at Lucknow, India, the wife of Major Jasper M. Woolley, I.M.S., of a daughter.

MARRIAGES.

BARNES—NORMAN.—On May 15th, at St. John's, Angell-town, Brixton, Lieutenant Howell Wood Barnes, M.B. Cantab., R.A.M.C., to Sarah Francis, youngest daughter of Frederick Norman, J.P., F.R.C.S.

HENRY—MILNE.—On May 15th, at St. Luke's Church, Chelsea, Arnold Kirkpatrick Henry, M.B., F.R.C.S. Irel., to Dorothy Kate Milne, M.D., B.Ch.

MONCRIEFF—LONGMUIR.—On May 15th, at the Church of the Holy Trinity, St. Andrews, Surgeon Leonard Alexander Moncrieff, M.B., R.N., to Hilda Constance Arnott, youngest daughter of the late Thomas Longmuir and of Mrs. Longmuir, Howard-place, St. Andrews.

DEATHS.

FIELD.—On April 10th, at Wittenberg, in Saxony, Stephen Field, Captain, R.A.M.C.

GOODDEN.—On May 9th, killed in action, near Ypres, Henry Wyndham Goodden, Lieutenant, R.A.M.C., aged 31 years.

PERN.—On May 9th, killed in action, Lieutenant Montague Pern, R.A.M.C., aged 26 years.

SIMPSON.—On May 10th, at Byron-street, Patricroft, William Allan Simpson, M.B., C.M.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE USE OF CHAMPAGNE IN SURGERY.

To the Editor of THE LANCET.

SIR,—I should like again to invite attention to my favourite treatment of surgical shock by rectal injection of a pint of good dry champagne. Since my first communication on the subject was published in THE LANCET of May 17th, 1913 (p. 1416), in which I dealt with the rapid improvement which followed subcutaneous injections of champagne, some local necrosis of skin followed in some later cases, and I abandoned the method in favour of rectal injection (THE LANCET, Sept. 20th, 1913, p. 863), which I have found equally rapid in action, and equally efficacious, without any after complication whatever. It has been the rule in this hospital during the past two years that in all serious operation cases the sister in charge of the patient brings with her a bottle of champagne and a funnel with long rectal tube to the operating theatre. The moment any evidence of shock appears two assistants promptly separate and elevate the legs and buttocks, and the sister administers the injection (pure). Marked reaction is usually established within three minutes. In my original letter I made a statement, which I am pleased to see confirmed by Lieutenant Haycraft in THE LANCET of March 20th, 1915 (Treatment of Acute Emphysematous Gangrene) that "champagne and pituitary extract is a combination that I can strongly recommend." And in the *British Medical Journal* of Jan. 31st, 1914, I stated: "In serious cases of ante-operative toxæmia we have found the placing of the patients out of doors, immediately after operation, to be of immense service, and during the early convalescent stage in such cases we have experimented purposely, and have proved over and over again that there is no drug or anything else equal to the daily administration of a pint of the best dry champagne."

In conclusion, I need only say that these statements have been emphasised by further experience. Soon after my article appeared in THE LANCET a friend forwarded me a French comic paper, in which were depicted a young lady and gentleman arm-in-arm doing a kind of goose-step out of a doctor's house, apparently full of "beans," after receiving their champagne injections "as recommended by Dr. 'Jhon' O'Conor"!—I am, Sir, yours faithfully,

J. O'CONOR, M.A., M.D. T.C.D.,
Senior Medical Officer, British Hospital,
Buenos Aires.
April 18th, 1915.

FLOATING KIDNEY.

A MEDICAL correspondent asks if a floating kidney can be easily diagnosed, and if when diagnosed an operation is indicated. The questions cannot be answered quite briefly. It is certainly possible to diagnose a floating kidney during life, for the normal kidney is capable of very slight movement, while a floating kidney can often be moved many inches from the place where it is found. In many cases it occupies habitually a lower site than normally. The question of operation is by no means easy. While some consider that the results of floating kidney are many and serious, and that in all cases an operation is eminently desirable, these views are not held by perhaps the majority of surgeons or physicians. It is fairly certain that in most cases a floating kidney gives rise to no symptoms, and the patient is none the worse for it, but when a patient is told that she has a floating kidney she begins to have many symptoms, and she ascribes them all to the floating kidney. In the large majority of cases an operation is not needed, and will do no good. It is rarely wise to tell a patient that she has a floating kidney, unless the surgeon or physician is certain that it is giving rise to important manifestations. There is, however, one condition which may be caused by movable kidney which may make an operation necessary. When the altered position of the kidney leads to a kinking of the ureter a hydronephrosis may arise, and this will steadily grow worse unless the kink is done away with.

DR. JOHN GEORGE CHAPMAN.

THE *Nottingham Guardian* of May 4th has published under the heading of "A Nottingham Author and Physician—Friend of George Eliot—Passages from Unpublished Diaries" a long account of a find among the old bookstalls at Sneinton Market, Nottingham. The find consists of some of the diaries of the late Dr. John George Chapman, who was for many years editor of the *Westminster Review* and a London publisher, who was intimately acquainted with many literary people of note, amongst them Charles Dickens and George Eliot, and his acquaintance with George Eliot is described with some detail in the diaries, which are three of Letts's little books dated 1851, 1860, and 1863. Chapman was a very interesting man. He started as a publisher, but took a medical degree at St. Andrews and gave up business. He practised in London at Somerset-street, Portman-square, and became known especially by his persistence in the efficacy of the successful treatment of cholera and diarrhœa by means of the spinal ice-bag, and delirium tremens and the treatment of cerebro-spinal fever by means of ice; also for a new method of treating paralysis by the application of cold or heat along the spine. He also wrote on the abuse of medical charity and on diseases of the nervous system. He died in 1894 in Paris, whither he had retired, as the result of being run over by a cab, and his death was announced in THE LANCET of Dec. 8th of that year.

WHAT IS A CONSULTANT?

To the Editor of THE LANCET.

SIR,—In answer to the question of "Enquirer" in THE LANCET of May 1st (p. 946), I think one may say—in England a consultant may be defined as a medical practitioner, a Fellow or a Member of the Royal College of Physicians or a Fellow of the Royal College of Surgeons, who only sees a patient with, or on the introduction of a general practitioner, and does not attend any patients except in consultation, thus corresponding to the barrister in the sister profession of the law. This is, however, purely a theoretical description, as I do not know anyone in London to whom the description could be applied, although all my medical life has been passed in or near London since 1879. I have heard that one consultant has a notice on his waiting-room table stating that he does not practise as a general practitioner, and I have also been informed that a Guy's man is really a consultant, but I have no experience of these two, and perhaps they may be mythical.

I am, Sir, yours faithfully,
A. CHARPENTIER.
May 12th, 1915.

SEVERE ILLNESS APPARENTLY DUE TO EATING RHUBARB.

M. L. J. (Bristol) writes:—"With reference to the letter of 'M.D.' in your issue of May 8th I had a somewhat similar experience, unmistakably due to eating rhubarb, some five years ago. My age then was about 50, and I should say that I have been all my life a sufferer from neurasthenic dyspepsia of an inveterate type, so that for many years the most rigorous expedients in diet have been necessary. One evening I ate some stewed rhubarb. Though it is not easy to produce emesis in me I was vomiting in a few minutes, was purged, and felt very ill. Bicarbonate of soda, with very small doses of liq. bismuthi and tr. opii, combined with copious use of milk (no other drink), raw eggs beaten up, and meat diet, after some days relieved the gastric symptoms, which then took the form of intense renal and vesical irritation, an abnormal quantity of urine being passed, the necessity to micturate obliging me to rise four or five times every night. With persistent use of milk and bicarbonate of soda the symptoms gradually wore off.

I attributed the poisonous effects to the oxalic acid in the rhubarb acting on a highly neurotic, dyspeptic, and gouty diathesis; but it has been suggested that they were possibly due to the effect of the tannic acid in the rhubarb on a gouty subject. Perhaps it was both. I have known of other people who were always made seriously ill by eating rhubarb."

AN INVITATION FROM HARROGATE.

THE Harrogate corporation has issued an invitation to medical men to visit Harrogate at any time during the next 12 months (excluding the period July 15th to Sept. 30th), and they are offered the free and unlimited use of the baths and waters and complimentary facilities and special rates connected with hotel accommodation. The opportunity is thus given of putting the claim to the test in regard to Harrogate taking rank with those well-known continental resorts now closed to the public on account of the war.

A MEDICAL PRACTITIONER'S DAY-BOOK.

Messrs. Robert Gibson and Sons, of 45, Queen-street, Glasgow, have published a convenient day-book (No. 4) of small size for the use of panel practitioners. It measures roughly $4\frac{1}{2}$ by $8\frac{1}{2}$ inches, and each opening is ruled for a month. Provision is made for the entry of 1440 names, with the necessary particulars required by the Insurance Commissioners. The book, which is compact, should serve to reduce the panel practitioner's clerical work. The price is 1*s*. net, or by post 1*s*. 2*d*.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—Philip Turner, J. D. Rolleston, Sidney Gilford): at 4.30 P.M.

Dr. C. O. Hawthorne: Case of Hemiplegia in a Girl aged 8.
Dr. H. Thursfield: Case of Defective Patellæ and Contraction of Limbs.
Dr. E. Pritchard: Cystic Lymphangioma in Infant.
Dr. E. Pritchard and Dr. M. Richards: Case of Polioencephalomyelitis.
Dr. J. D. Rolleston: Case of Ectrodactyly.
Dr. E. L. Goffe: (1) Case of Deformity of the Left Hand with Constriction of the Right Forearm; (2) Case of Dextrocardia.
And other Cases.

Specimen:
Dr. P. Figdor: Pericarditis in Diphtheria.

Short Paper:
Dr. C. O. Hawthorne: Case of Tuberculous Meningitis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham): Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie). 4.30 P.M., Special Lecture:—Dr. J. B. Banister: The Treatment of Puerperal Sepsis.

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. H. D. Gillies). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting).

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. Gillies). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients. 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M. Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.			
One Year	£1	1	0
Six Months	0	12	6
Three Months	0	6	6

TO THE COLONIES AND ABROAD.			
One Year	£1	5	0
Six Months	0	14	0
Three Months	0	7	0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Arris and Gale Lecture

ON

THE INFLUENCE OF THE ARBOREAL HABIT IN THE EVOLUTION OF THE REPRODUCTIVE SYSTEM.

Delivered at the Royal College of Surgeons of England on March 22nd, 1915,

By FREDERIC WOOD JONES, D.Sc. Lond.,
PROFESSOR OF ANATOMY, UNIVERSITY OF LONDON; LECTURER TO THE LONDON SCHOOL OF MEDICINE FOR WOMEN.

Mr. President, Ladies, and Gentlemen,—The influence of environment upon the structure and organisation of animals is a matter upon which nowadays everybody is well informed. Like so many of the ideas popularised from the work of Darwin, this factor of evolution has tended to become condensed into words and phrases which often hinder, rather than help, the progress of new thought and further research upon the subject. In 1846 when, as newly appointed professor, John Goodsir delivered his first opening address, he chose for his subject "The Progress of Anatomy." "There is nothing," he told his audience on that occasion, "which has more retarded science and philosophy, and the kindred subjects on which human reason has been employed, than the introduction of terms with conventional meanings. Men come at last to defend the terms, as if they were the truth, and to mistake an artificial shadow for the substance required." Goodsir's warning was doubtless needed in 1846; but its need was very much the greater during the upheaval of the next few decades; and to-day no better text could be taken by any man embarking upon a career of teaching others.

The Arboreal Habit and Evolution.

That habits and surroundings produce their effects in alteration of animal structure is perfectly obvious. The sum total of the outward appearance of an animal tells very truly, as a rule, what sort of life the animal leads and amidst what surroundings it leads it. But it is when we go beyond the mere outward appearance of the animal and examine the more minute details of its separate systems and organs that the wonder of adaptation is forced upon us, and the futility of any catch phrase to sum up this wonderful influence becomes apparent.

If we turn to Man and examine his special peculiarities and compare them with those of his nearest neighbours, and these in turn with those of their more remote kinsfolk, we see a sequence of modifications impressed upon the plastic animal body by life habit and environment; and if we were to ask what special life habit has been at work to produce the distinct configuration of the human body, we should probably be told by most people that it was the assumption of the orthograde posture—the habit of standing and walking upright. No doubt this assumption of the upright posture has done much in putting the finishing touches upon the evolution of the human stock; but we must be careful to give it no more than its real value. Long before the fashion of walking upright had been even foreshadowed in the crouching gait of the half-finished product, a potent factor was at work producing those changes which ultimately permitted, and culminated in, the erect carriage. This factor which paved the way, and to which most of the general changes of human and primate bodily conformation are due, was undoubtedly the arboreal habit—the habit of climbing and living up trees, instead of dwelling upon the ground beneath.

We are apt to lay too much stress upon Man's descent from the branches. It was not coming down the tree that was so important in the evolution of the human stock; it was the climbing up, the first step towards the freedom of the branches, that counted in the progress of the mammalian stock from which Man has sprung. In brief manner it might be said that this line of mammalian development could be summed up in the saying that some small and humble Insectivore—probably not very unlike our modern Tree Shrew—climbed a tree, lived and evolved among its branches, and, after long ages, walked down to the earth again in the guise of the highest of the Primates.

If the influence of the arboreal habit is not always obvious when we regard only the changes in the general bodily conformation of those Mammals which are upon the line of human evolution, it is, nevertheless, very clearly indicated when we turn to the details of change in separate systems and organs. With regard to the reproductive system, with which this paper is especially concerned, it seems to me that we can never understand the evolution of this system unless we appreciate the necessity for change of habit, and for adaptation of structure, imposed by maternity among the branches.

This, then, is the scope of my lecture—the study of those modifications brought about in the reproductive system by arboreal life, and this especially among those Mammals which are upon the line of the evolution of Man. It is when we attempt to define what Mammals are here considered to be landmarks on the path along which the human stock has evolved that difficulty is encountered. This difficulty I propose to overcome in a somewhat dogmatic manner by appealing to the type of external genitalia as the criterion by which a Mammal is regarded as being upon the line of the human stock or no.

Types of Mammalian External Genitalia.

In the Arris and Gale lectures which I had the privilege of delivering last year,[1] I discussed this question and arrived at the conclusion that there were two main types of mammalian external genitalia, and these two types I labelled for the purpose of the moment, and purely for convenience, as Type A and Type B. Perhaps it is justifiable now, as a mere matter of temporary expediency, to give more convenient names to these two types; and I propose to designate Type A as Cloacaexplicata, and Type B as Cloacaimplicata. This tentative nomenclature is proposed as indicating the main features of cloacal evolution which takes place in these two types; for in Type A the cloaca is obliterated during development by eversion, while in Type B the cloaca is obliterated by the infolding of the cloacal margins. I will go no further into this question now than to say that Type A is that which is characteristic of Man, and with Man an assemblage of lower mammalian forms. It is therefore those lower animals of which the external genitalia conform to this Type A that are considered here as being upon the line along which Man has evolved.

---

[1] The Lancet, April 11th and 18th, 1914.

In my previous lectures I did not attempt to give any detailed list of the individual mammalian forms which fall into this line. Any classification furnished now must of necessity be incomplete, for until the developmental phases of the external genitalia of any particular Mammal are studied some uncertainty may be entertained concerning its true position. Nevertheless, sufficient material has already been examined to enable the general outline to be perceived, and to detect the presence of Mammals having this Type (A) of external genitalia in retrograde series from Man downwards.

Tracing this type towards its parent stock we are led to that primitive and central group of Eutherian Mammals, the Insectivora. It was Huxley's opinion as a young man that a primitive member of this group represented as nearly as possible the picture of the root stock of the Eutherian Mammals, and after another 30 years of work this view, put forward in his youth, was still more strongly adhered to. A more recent pronouncement of the same idea is that of Matthew (1909), who has declared that "the Insectivora represent more nearly than any other order the central stock from which the various groups of placental Mammals have descended."

TYPES OF EXTERNAL GENITALIA IN INSECTIVORA.

One interesting fact that has emerged from the present investigation into the method of formation of the external genitalia is that within the limits of this group are comprised not only animals whose cloacal closure is carried out as in Type A and as in Type B, but several forms in which the cloaca remains permanent throughout life. Here, then, is evidence of a primitive and generalised central position of the Insectivora such as was believed in by Huxley. The Insectivora form the basal meeting point of the Cloacaexplicata and Cloacaimplicata, and at this meeting point is found the simple cloacal Eutherian Mammal from which presumably both were derived. We might, if this matter of tentative nomenclature and classification has not already gone far enough, say that the members of the great Order of Insectivora might be divided into three groups—the most primitive group having the cloaca as a permanent structure (Cloacaperta), the second with outfolded cloaca (Cloacaexplicata), and the third with infolded cloaca (Cloacaimplicata).

There are several species of inconspicuous and little-studied Shrews in which the cloaca persists in as perfect a form as that seen in the Reptile or Bird. I think that these small cloacal Eutherians have not had sufficient importance assigned to them in the study of the phylogeny of the Mammals. There appears a tendency to assume that the cloaca of these animals is not a true one, or is a mere adaptation in some cases to an aquatic habit. By no means all these cloacal forms are aquatic, and there seems to me no doubt that the cloaca of the Insectivora is in every way as true a cloaca as that of the Reptiles or of *Ornithorhynchus* or *Echidna*. So far I have examined the microscopic details of *Blarina meridensis* from Venezuela and *Crocidura bottigi* from Abyssinia, and there remains a very large number of other forms still to be examined.

Again, a large number of species of Insectivora pass from the cloacal stage to the non-cloacal during embryonic development in the manner that I have described as typical of the Cloacaimplicata, and in this way mark the road which the Rodentia and Ungulata follow in their development. Some forms, such as the common mole (*Talpa europea*), have carried this method of development to an extraordinary degree, so that the males and females come to possess an outward sexual appearance that is identical; and again in this they are the pioneers of a development that is also displayed in Rodentia (*Capromys pilorides*), and even Carnivora (*Hyæna crocuta*). But of more interest to us in the present study is the fact that some Insectivora—or animals usually classed among the Insectivora—close the cloaca during embryonic development in the manner typical of the Cloacaexplicata, typical of the Primates and of Man.

The Tree Shrews.

These interesting animals are those known as the Tree Shrews, and called by the Malays "*Tupai*," a name which they share with the squirrels, that are true Rodents. They are of more than a dozen species, all inhabiting the Indo-Malayan region, and all possessing that rough general likeness to squirrels which has led to this very simple case of convergence being foolishly magnified into an example of protective mimicry on the part of the Insectivore. The *Tupaias* are active little animals, hunting their insect food amongst jungle from sea-level to the tops of mountains 5000 feet high. Like most arboreal forms, they have so far emancipated the fore limb from the duties of mere progression as to use their hands for conveying food to their mouths, and most have the feathered tail which, like that of the squirrels, aids them in their arboreal activities.

They have been assigned to rather different zoological positions by systematic zoologists. Their affinities are so varied that now one character and now another has been taken as indicating near kinship with several different types. From the rest of the Insectivora they and the *Macroscelididæ* are distinguished by possessing a cæcum; and these two groups are now, as a rule, combined as the *Menotyphla* (Lecke, 1884). From the *Macroscelididæ* (Cape Jumping Shrews) they differ anatomically in several characters, one of the most important being that whereas the orbits of the Jumping Shrews are not completely encircled by bone, those of the Tree Shrews approach the Lemurs and higher orders in this respect and have an entire bony ring.

It is not alone in the form of its external genitalia that the *Tupaias* show conditions unlike those seen in other insectivores and approximate those found in other and higher orders. In many features of the skull and the brain they are very much advanced from the moles and shrews and their allies; and in these features as well as in some of their dental characters they show definite affinities not only with the Lemurs, but also with Galeopithecus and the Bats.

But there is one point of the greatest interest in the conformation of the external genitalia of the male *Tupaia*; the testes, unlike those of the Insectivora as a class, are permanently descended into a scrotum, but this scrotum is situated unusually far forward, so that the testes lie to the sides of the penis rather than behind it—a condition that can only be described as intermediate between that seen in the Marsupials and that typical of the Eutherian Mammals.

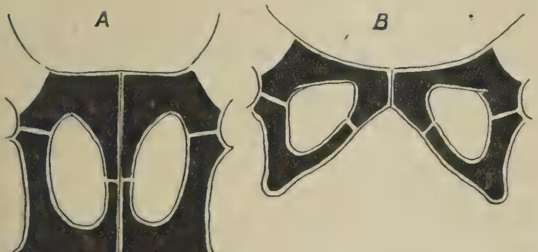
THE DEVELOPMENT OF THE PELVIS.

One fact has become more and more striking to me as I have attempted to follow mammalian affinities by the criterion of the external genitalia, and it is that the animals which follow the type of the Cloacaexplicata are essentially tree-climbing creatures. In attempting to unravel this story we are led by easy stages through the Lemurs to *Tupaia*, a typically arboreal animal; but we also find ranged in this series other animals which, though thorough tree climbers, seem to be linked by no easy stages with the stock we are considering.

Although in the finding of Primate linkages in steady sequence back into the Insectivora one may feel tolerably certain that one is dealing with true phylogenetic affinities, some doubts and some questions must arise when such aberrant animals as certain of the Edentates fall into the same group. But even should I suggest that, judged by their external genitalia alone, the Sloths were allied to the Primate stock, I should be going no further than others have gone by using altogether different criteria. Still, in the face of the possibility of this being a case of convergence due to the common arboreal nature of the two sets of animals, a great many questions must be asked and answered before we make any suggestion as to the zoological affinities of certain Edentates and Primates from the study of their genitalia. Is it possible that the arboreal habit can in itself create, or alter, a special type of external genitalia such as I have described under the name of Cloacaexplicata? I believe that the answer to this question may be attempted, not by the study of the external genitalia in themselves, but rather from a review of those general pelvic conditions which are found in association with the different types of external genitalia.

The bony framework of the pelvic cavity varies enormously in its general architecture among the different mammalian orders, and in some ways this variation appears to be haphazard and to bear but little relation to accepted zoological affinities. We may assume that the most primitive of the Mammals possessed a pelvic girdle akin to that seen in Sphenodon and in the imbricate reptiles; indeed, such a pelvic girdle persists very perfectly in the existing Monotremes. In such a pelvis two elements, the pubis and the ischium, meet ventrally, forming an ischio-pubic symphysis. (See Fig. 1, A.) This form of pelvis, in which there is an ischiatic as well as a pubic symphysis, is found with various modifications in Ungulates, in Rodents, in most Marsupials, in most Carnivores, and in some of the Insectivora. The ventral wall of the bony pelvis is long in all these animals, and this factor in itself produces some important characteristics of the reproductive system. The female genital tract between the pelvic uterus and the post-ischiatic vulva must be long, and the copulatory organ of the male must be of proportionate length. These changes will be referred to again, but we might instance here the long female vaginal and urogenital sinus segment, and the elongated copulatory organ in the male associated with the elongated symphysial area of the typical Ungulate.

FIG. 1.



Primitive mammalian type of pelvis (A) contrasted with human type (B).

If we turn at once to the human pelvis the outstanding fact is that the ischia have ceased to meet in the middle line, and with their splaying aside only a comparatively small portion of the pubis itself enters into the formation of the symphysis. (See Fig. 1, B.) Here the ventral wall of the pelvis has, as it were, been split open from its caudal end, and the ischia and also a part of the pubis have been thrust aside. With this shortening of the ventral wall of the pelvis the female genital tract has become very considerably shortened; the urogenital sinus is entirely lacking, and the copulatory organ of the male is reduced in harmony.

Influence of the Arboreal Habit on the Pelvis.

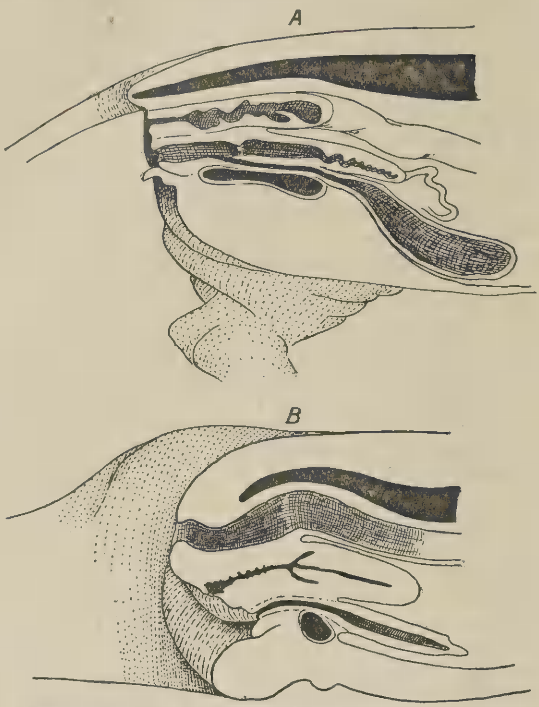
All sorts of intermediate stages exist between the partial pubic symphysis of Man and the complete ischio-pubic symphysis of the Ungulates and Rodents. We have been accustomed to regard the pelvis of Man as the typical orthograde pelvis—the outcome of the erect posture; but I would rather look upon it as the perfected tree-climbing pelvis—the pelvis that has been evolved by the arboreal habit. If in respect to symphysial development we try to match the human pelvis with any example taken from the lower Mammals we shall find it paralleled and even surpassed in the Sloths.

Within the limits of the Primate series the evolution of the human type of pelvis is particularly well seen, a pure pubic symphysis (in which the pubis only enters and to a varying degree) is present in all arboreal types, but in such pronograde forms as *Cynocephalus* and all the dog-like baboons there is a very complete return to the ischio-pubic type of symphysis. A striking contrast in the study of adaptations as opposed to status in zoological classifications is seen in the "open" pelvis of the arboreal *Lemur varia* and the "closed" pelvis of the pronograde *Cynocephalus anubis*. Among the Rodents, the Squirrels exhibit a more open type of pelvis than do their more terrestrial relations, and the semi-arboreal Felines have made a distinct start in the same direction.

Although there are some striking exceptions in the general application of any theory, I believe that it is, on the whole, the altered poise of the body upon the hind limbs that occasions this variation in the development of the symphysis. This alteration of poise is, for the most part, the outcome of the habit of climbing as opposed to mere pronograde four-footed progression upon the level surface of the earth. As a general rule we may say that where the hind limbs bear the weight of the body in the pronograde position there tends to be a complete ischio-pubic symphysis; where the hind limbs bear the weight of the body in the modified position of tree-climbing there tends to be a reduction of the symphysis, culminating in an abbreviated pubic symphysis; and where the hind limbs take no share whatever in supporting the weight of the animal the symphysis tends to be wanting altogether.

We may therefore say that it is, at any rate, a possibility that the arboreal habit has influenced the extent of development of the ventral junction of the bones of the pelvic girdle; that it has tended to bring about a shortening of the area of contact and to limit this area to a portion of the pubis only. In this way a shortening of the female genital tract has been effected, and hand in hand with this abbreviation a corresponding reduction of the male copulatory organ has taken place. (See Fig. 2, A and B).

FIG. 2



Median sections of the pelvis of (A) a full-term female pig embryo and (B) a full-term female human embryo. Note the apparent outfolding of the female genital tract in (B) where the symphysial area is reduced.

The Pelvis and the Type of External Genitalia.

But I suspect that the splaying out of the ventral portion of the pelvis has done more than this, and that it has, in some measure, influenced the type of external genitalia just as it has modified the type of the lower segment of the internal genitalia of the female by reducing and finally suppressing the long chamber which is common both to the urinary and the reproductive systems.

The fate of the Mammalian cloaca is bound up with the modifications of that portion of the body upon which it is primarily situated, and in the early embryo the cloacal site involves that area in which the ventral union of the pelvic elements ultimately takes place. It is therefore not unlikely that the evolution of the cloaca will in some measure be modified by the extent of this ventral union. There is certainly very definite evidence to show that with the opening out of the symphysis the cloaca tends to be outfolded (type of Cloacaexplicata) in the wide space left between the diverging ischiopubic rami, while with the complete closing up of the symphysis the cloaca tends to be infolded (type of Cloacaimplicata) behind the united ischiatic rami.

In this way it is possible that the arboreal Sloths merely show a convergence towards a Primate condition, and that type Cloacaexplicata may (in such cases) be the result of symphysial modifications produced by the arboreal habit. We shall see later that in several other features of their reproductive systems the Sloths approach the Primate condition, but in these other features also we may see the influence of the common arboreal habit as a rival to the claims of real zoological affinity.

TRANSITIONS FROM TERRESTRIAL TO ARBOREAL LIFE.

Apart altogether from these modifications which may be induced by mere bodily poise, and the discussion of which must be left for the present in a rather problematical stage, there are others impressed upon the reproductive system by the stern realities of the arboreal life. In order to follow these modifications we may picture a primitive Eutherian Mammal, situated right at the base of the Cloacaexplicata, and trace the influence of the arboreal habit upon its general reproductive activities. Such a hypothetical animal is perhaps most nearly represented by those fossil remains of Shrews which occur in the Oligocene of North America and Europe, or going still further back to the Insectivora primitiva of Osborn, which, including the Stylacodontidæ, are as old as the Jurassic.

Like modern Shrews this animal, while hunting for its insect prey upon the ground, would nevertheless show an extraordinary activity, and a highly developed power of climbing, such, for instance, as is often manifested by *Sorex minutus*. We must now imagine it becoming the pioneer of the route which *Tupaia* has followed and adopting the habit of ascending trees in search of its insect food. Such transitions from terrestrial to arboreal searches for insects are seen, of course, very beautifully in other orders, such as Reptilia and Amphibia.

It is now necessary to see what was the probable condition of the reproductive system, and what would be the probable effect of an arboreal life upon such a creature.

Factors Influencing the Number of Offspring.

In the first place we may assume that, like most terrestrial Insectivora with which we are acquainted, this animal would produce large numbers of offspring at a birth. Among the terrestrial Insectivora the maximum of mammalian fertility is displayed; very large litters are produced by many species, and *Centetes* is known to produce 20 young at a birth. This is, however, an unusually large family for a Mammal, and taking our common English Shrew (*Sorex araneus*) as a guide we might suppose its litters to average seven or eight with a common advance to ten or even more young. We would picture it as having a large series of nipples, thoracic, abdominal, and inguinal, to supply the wants of this large family; and we would expect the female to possess a uterus consisting in the main of two long "uterine horns" in which these multiple embryos could be accommodated.

How will arboreal life affect such an animal with such a family? It is no mere speculation to say that large families become inconveniences among the branches; and that the disadvantage of large families will be felt in two ways. There is first the disability imposed by pregnancy, and secondly the difficulty of accommodating and nursing a large family up a tree. It is not only in arboreal life that these difficulties are encountered, and in many different types of Mammals and in many different situations they have been solved. The solution has always ultimately been the same—the reduction of the family.

That the climbing activities of the female, when pregnant of a large litter, would be hampered seriously seems obvious; and yet the reality of the disability becomes still more striking when we study those curious pelvic changes which are well known to occur during pregnancy in many large-littered animals. In some Rodents stretching, and partial solution of the continuity, of the pelvic ligaments go on to such a degree that the pelvis becomes more or less unstable as a pivot for the hind limbs, and ordinary terrestrial progression becomes reduced to a mere waddle. Such a condition of the female is obviously unsuited to activities among the branches.

Large families can therefore only be indulged in, as a rule, by animals the females of which may be exempted from any very exacting activity during pregnancy. Such is a general axiom among the Mammals, and leaving altogether the stock with which we are most concerned, examples of its truth are readily furnished in many Orders. Herbert Spencer gave much thought to the well-known instance of the relative fertility of the hare and the rabbit. Much of his speculation was no doubt true; but we must not overlook the fact that a doe rabbit's home is safe in a burrow, while the female hare has no such protection. And the same cause that has led to the reduction of the hare's litter has been at work, with even greater force, among the Ungulates. Again, in aquatic life the same disability is felt, and the picture of the pelagic life of the whales makes the second axion—that where there is no nursery there will be no large families—more real.

This factor would no doubt be felt severely by the pioneers of arboreal life, for it is easy to imagine the difficulty of dealing with large numbers of helpless offspring which are unable to follow their mother about the branches. The difficulty is one which the animals with a leaning towards arboreal life have attempted to overcome in more ways than one. Of course, the female may descend from the trees at this time and produce and rear her young upon the ground; but this leads at best to a life that is only semi-arboreal, and there are many animals (such as several Felidæ, for example) which lead such a life.

Nest Building.

The next step is the attempt to provide some nursery for the progeny in the adopted home of the parent; *this is the dawn of nest building*. Most of the terrestrial Insectivora construct rather more than a mere lining for the retreat in which the young are born, and many are distinguished as nest builders. Those shrews whose domestic habits have been at all studied are known to rear their young in very well constructed nests. Such ability in nest building may be carried further even by terrestrial forms. Our common English Shrew (*Sorex araneus*), although as a rule resting on the ground, is capable of an advance in the direction we have been imagining, and it has been known to construct a very good nest 3 feet up in the branches of a young spruce fir.

What *Sorex* can do on occasion it would seem *Tupaia* does under ordinary circumstances. The nests of some of these animals have been studied, and although with regard to *Tupaia minor* Charles Hose did not feel certain if the *Tupaia* had made its own nest or used one already built by a bird, there would seem every reason to believe that with most species the nest is the work of the animal itself. Our hypothetical Insectivore, therefore, probably found nest making easily within its powers, and so made the conquest of the branches more certain.

Turning again to other stocks we see how readily nest building is adopted by arboreal or semi-arboreal Mammals. Our harvest mice (*Mus minutus*) are adepts, and dormice (*Muscardinus*) and squirrels (*Sciurus*) and many other Rodents construct extremely good arboreal nurseries. Again, among the Marsupials certain species of *Phascologale* adopt the habit of arboreal nest building, and these animals suggest some speculations that will be dealt with in their proper place.

Reduction of Number of Offspring at a Birth.

Nest making was an early solution of the arboreal nursery problem among the forerunners of the Primate stock. *Tupaia* retains the habit, and more remarkable still that aberrant Lemur, *Chiromys*, resorts also to the same practice; according to Mr. L. Baron "it builds a nest about two feet in diameter of twigs and dried leaves in the dense foliage of the upper branches of trees. The nest is entered by a hole in the side."

Nevertheless nesting is obviously a habit that must be left behind in the progress of evolution; although convenient for small animals with large litters, it becomes exceedingly inconvenient for larger species, and nest building we may look upon as merely a temporary expedient in the development of the Primate stock—an expedient adopted only so long as the production of large litters was prevalent. The typical Lemurs have, so far as I can learn, abandoned the habit; and it is to be noted that in the special case of *Chiromys* the nest that is built is probably not merely a simple nursery, for it provides a shelter for the adult in the same manner as the branch platforms constructed by some of the higher apes. In *Chiromys* the ultimate factor—the reduction of the family—has already come into play and only a solitary offspring is produced at each birth; nevertheless, the retention of the nest nursery has probably led in this instance to the development of one anatomical peculiarity which will be discussed later.

The end of all the adaptations of reproductive habit to arboreal life is the reduction of the number of offspring produced at a birth. All those truly arboreal Mammals which mark the line of human descent display this relative infertility. Among the Lemurs, although two young are occasionally produced at a birth, it is the rule that only one offspring is born. With all the *Cebidæ*, *Cercopithecidæ*, and *Simiidæ*—the whole class of the Monkeys and Apes—a solitary baby is alone produced at each pregnancy, as a rule, but upon occasion two are born.

There is a very widespread belief among the natives of Java that when a monkey has a family of more than one it is the custom for the mother to let them cling to a branch, and to rear only that one which remains clinging after the branch has been well shaken. I know not what reliance is to be placed upon the accuracy of this story, but it has been vouched for by a very observant Englishman, and it is not unlikely that the tradition represents, at any rate, a summary of the working of one factor causing the reduction of arboreal families.

Further back in the mammalian story among the Endentata such truly arboreal animals as the Sloths (*Bradypodidæ*) produce but one young at a birth, and the arboreal Pangolins (*Manidæ*) not more than two.

The Emancipation of the Fore Limb.

There is another, and a most important, change produced by arboreal life, and although this new factor has primarily no relation whatever to reproductive habit, and ultimately leads to the most far-reaching developments altogether outside this function, nevertheless it exerts its influence upon the reproductive system in some remarkable ways. This new factor may be named "the emancipation of the fore limb"; and it makes itself evident in varying degree in all arboreal types. The fore limb becomes freed from the sole use as an instrument of mere progression in arboreal life. The important story of the emancipation of the fore limb, and all that it leads to, cannot be told here; but a brief summary of the steps, in as far as they concern the reproductive habit, is necessary.

In arboreal progression the hand grasps the branches, instead of the hoof or the paw being planted upon the ground; and from this beginning it becomes a member capable of grasping other things; of being used for a multiplicity of purposes from catching insects or picking leaves to conveying the food, so obtained, to the mouth. Among other results of this modification is the ability of the mother to grasp the young and the young to grasp the mother. *This is the dawn of nursing.*

Among the Lemurs it is the rule for the young to grasp the ventral fur of the mother, and in many species the mother displays but little ability to hold or carry its offspring in its arms; indeed, according to Charles Hose, *Tarsius spectrum* has made so little progress in this direction that at times it carries its young in its mouth after the fashion prevalent among cats.

The young of *Nycticebus tardigradus* is so small, and clings so closely among the dense fur of its mother's ventral surface, that it is extremely difficult to find and dislodge. Even native dealers will occasionally sell two animals as one, so difficult is it to detect the tightly clinging young. In this species, and, I believe, in other Lemurs, the young one sometimes has its head towards its mother's head and sometimes towards her tail. In the animals that I have had in captivity the common position was for the infant to grasp the mother's chest with its legs, and cling to the abdomen with its hands, its head being pressed against the mother's inguinal region. With *Lemur catta*, apparently, the tail of the young assists it to hold on to its mother, a method that has been carried to great perfection in truly prehensile-tailed animals of other stocks such as *Didelphys lanigera* among the Marsupials.

Care of their Young by Monkeys.

Among all the Anthropoidea not only can the baby cling to its mother, but the emancipation of the fore limb has proceeded so far that the mother can hold and nurse the young. In most monkeys the young clings to the mother with its face against the mother's chest, its hands gripping the fur of her sides and the feet grasping her loins, and so travels back downwards in ordinary progression. This is the method in all the Old World monkeys that I have seen either in a state of nature or in captivity, and it is that usually described as typical; but Bates, speaking of *Uacaria calva*, says: "The mother, as in other species of the monkey order, carries her young upon her back." If this indicates that there is a real difference in the nursing habit of Old and New World monkeys, or simply means that Bates was observing rather older infants, I have not sufficient evidence to decide.

When the mother is at rest, however, there is no doubt as to the method of holding the young; and everyone must have noticed what Owen describes as "a very human fashion" of nursing typical of all monkeys. The very perfection of its likeness to human nursing renders any description superfluous but nevertheless the influences of this factor must be noted, for in some ways they are so very far-reaching in the advance towards higher conditions.

We have noted before that in situations other than the tree tops it has been necessary to limit the family for the reason that no natural nursery is to hand; but it is the peculiarity of the tree-top baby that it has a real infancy, and of the tree-top mother that in her is developed to the full the whole sum of attributes comprised in the expression "maternal care."

Among large numbers of the Ungulates (for example, the Horse) the offspring knows no nursery and is usually solitary; but it is born very mature and has but little childhood; for it must be prepared to flee at its mother's side upon the approach of danger. The arboreal baby, on the other hand, is born immature—its period of infancy is prolonged, and throughout its long stage of helplessness it must be carried and cared for by its mother. A very exact parallel is seen among birds, for the ground-nesting species (such as *Rallus Philippensis*, of which the young is running for its life in the undergrowth less than an hour after it has chipped its shell) contrast sharply with the helpless young hatched in the tree tops.

This paper is an anatomical one, and it is not intended to trespass into the psychical advances initiated by these changes; and it is unnecessary to point out the influences in psychical evolution exerted by such factors as maternal care, infantile dependence, and the formation of the family. In brief it may be said, from the eugenic point of view, that arboreal babies tend to be few but well looked after; and, from the psychical point of view, that the prolongation of infancy paves the way for social life and all the mental advances consequent upon it.

MAMMARY GLANDS.

With the anatomical changes, however, it is necessary to deal more fully. It has already been pointed out that the non-arboreal Insectivora have a large number of mammary glands and nipples; indeed, it is among these animals that perhaps the most complete mammary series is seen. *Centetes* possesses as many as 11 pairs of functional mammary glands and teats, and *Solenodon* has the distinction of retaining the most caudal glands seen in any animal, for the posterior nipples are carried on the root of the tail behind the buttocks.

Now, as a general rule, there is a very natural agreement between the number of pairs of functional mammary glands and the number of offspring produced at a birth. With the reduction of the family the reduction of the mammary series goes hand in hand.

In *Tupaia* with its many offspring reared in the nest the mammary series is still large, and pectoral, abdominal, and inguinal nipples are all present. In all other members of the Primate stock, however, the reduction of the family has led to reduction of the nipples and mammary glands. This reduction takes place in no haphazard way; only so many pairs are retained as are required for the nursing of a normal litter, and the pair or pairs in the series which are ultimately selected for persistence are those which are most convenient in the nursing habit of the mother.

It is the fashion of suckling—a fashion ruled by convenience—that determines which members of the whole linear sequence are retained as functional sources of nourishment for the young. All other members of the series undergo an atrophy, either complete or in part; nipples may persist, but milk-secreting glands disappear when function does not demand their existence. As a general rule it may be said that reduction of the mammary series first takes place in the intermediate—lower thoracic and abdominal—regions, the functioning glands persisting at the extremities of the series. The election of the distal members of the series as permanent mammary structures is demonstrated widely in the most diverse types of Mammals in which mammary reduction takes place in response to the lessened demands of a smaller family.

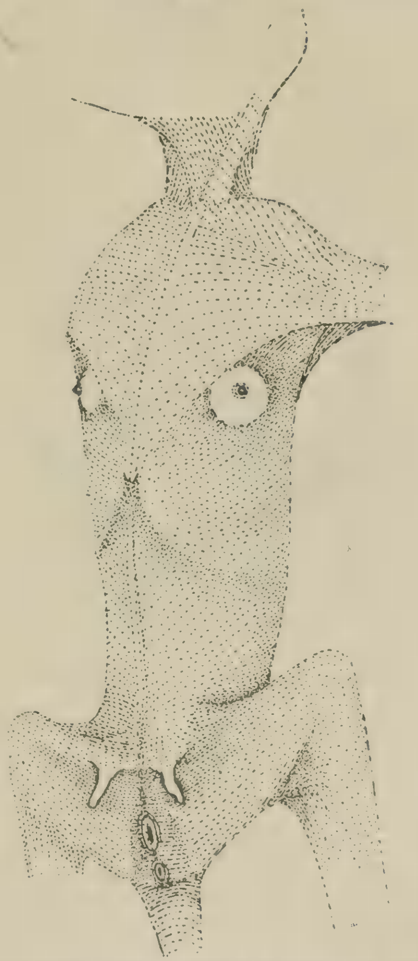
The functional element of convenience is perhaps best seen by turning at first to members of other stocks than that with which we are mainly concerned. In the mare, as an example of the true Ungulates, the mammary glands and nipples are just in advance of the vulva—a fact which arrested (and to good purpose) the attention of John Hunter. As a mare suckles the foal she can look all round for danger, she can keep her eye on the foal, she is able to graze unimpeded by her suckling offspring, and she can at once break into a trot if alarmed. With the elephant, on the other hand, it is the most cephalic pair of the mammary series that is retained. An elephant cannot flex its spine as a mare can; she could not look behind her at a calf suckling from inguinal nipples, nor could she control it with her trunk as nursing elephants are accustomed to do. The elephant calf therefore suckles from axillary nipples, where its mother can take care of it while she grazes with her trunk unimpeded by the presence of the suckling. The difference in position of the permanent mammary glands in the mare and elephant is therefore probably the outcome of convenience, ruled by the bodily conformation and life habits of the parent animal.

Anchoring Nipples.

Among the lower members of the Primate stock a mammary condition of the greatest interest is present. We have seen that among the Lemurs the young clings to the ventral fur of the mother with its back downwards and its head either directed towards the mother's head or towards her tail. This habit has led in most of the Lemurs to the retention of two pairs of distal nipples—a pectoral pair and an inguinal pair. The subsequent history of these nipples is correlated with the nursing habits of the different species. In some Lemurs the pectoral pair becomes predominant, while the inguinal pair degenerates, and in at least one species the reverse development is seen.

In captive specimens of *Nycticebus tardigradus* I have studied the functional meaning of these nipples. When the mother is moving about, climbing, eating, or searching for food, the young one, as a rule, has its head pressed against her inguinal region, and mother and offspring are opposed head to tail. In this attitude the young buries its face in the inguinal fur and grasps an inguinal nipple in its mouth. The position assumed by the young under these circumstances is doubtless to permit a greater freedom of movement to the mother when leading an active life among the branches. I do not know if the young *Nycticebus* obtains any nourishment from these inguinal teats, but I am inclined to believe that it does not, for obvious suckling takes place when the mother is at rest, and the baby, reversing its position, seizes a pectoral nipple. Doubtless in some forms these inguinal nipples are associated with functioning mammary glands and are a source of nourishment for the young, but I know no observations on this point. It is certain, however, that the general fate of these structures is that they become mere skin appendages unassociated with mammary glandular tissue, and thus cease to function as organs for the conveyance of milk to the offspring. (See Fig. 3.)

FIG. 3.



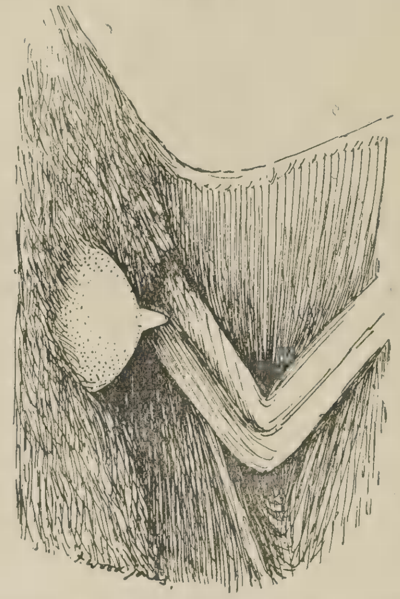
Reduction of the mammary series as it is seen in most Lemurs and some Bats. The pectoral mammary glands are functional milk-secreting structures, but the inguinal pair are reduced to the condition of "anchoring nipples."

Such nipples I shall call "anchoring nipples," for they serve merely to provide a firm basis to which the young may tether itself by its mouth. "Anchoring nipples" do not by any means degenerate, but become firm and elongated structures, which, though mere skin appendages, are reminiscent in their form of the Marsupial teat, which is an anchoring as well as a milk-supplying organ.

It is, perhaps, best to note here that anchoring nipples are not confined to the Lemurs. Among certain families of the Bats they are well developed, for the young of these animals clings to the mother's ventral surface and attaches itself to an inguinal anchoring nipple while the mother is in flight, but suckles from a pectoral nipple when the mother is at rest. This condition is exemplified in most of the common species of rhinolophid Bats, but the details have been especially noted in the literature in the case of *Rhinolophus ferrum-equinum* by Rollinat and Trouessart, who have named these nipples as the "faux tétons du pubis."

The position of the Cheiroptera with regard to the Primate stock, which we are now considering, will be noted later; but it is of interest to observe here the identity of mammary development in the Lemurs and in certain members of this Order. It will be recalled that it was the possession of a pair of pectoral mammary glands by the Bats that decided Cuvier in placing them among the members of his Primate order. (See Fig. 4.)

FIG. 4.



The remarkably human type of pectoral mammary gland of a Bat (*Brachyphyllum cavernosum*).

There is, however, at least one Lemur—the aberrant Chiromys—in which the inguinal nipples are apparently not reduced to the condition of anchoring nipples, but remain associated with the functioning mammary gland and are the source of infantile nourishment. According to Owen Chiromys possesses "but one pair of nipples situated about an inch and a half in advance of the vulva." I should imagine that the retention of inguinal nipples and mammary glands in this animal was probably the result of its nursing its solitary offspring while lying on its arboreal platform. The nest-building habits of this curious Lemur have been mentioned previously, and this habit, taken in conjunction with the fact that Chiromys produces but one offspring at a birth, possibly accounts for the retention of a pair of inguinal mammary glands as a matter of pure convenience in nursing the offspring in a nest. Chiromys must, however, be considered as an exception in this particular to the general trend of evolution in the Primate stock, for the the tendency is for the inguinal anchoring nipples to wane while the pectoral mammary nipples increase in size and importance.

Functional Explanation of Mammary Development.

This process takes place step by step with the increasing ability of the mother to grasp the baby. When the mother can hold and carry the baby the inguinal anchoring nipples are no longer of use and they undergo an atrophy; the infant being nursed in the arms and held to the more convenient pectoral nipples, the glands associated with these nipples become enlarged, and ultimately, in the higher members of the Primate stock, become the sole representatives of the long linear series of the lower Mammals. It is, however, worthy of note that even in the human female inguinal nipples may reappear. Such a case is that of a woman described by Testut and quoted by Blanchard and Rogers Williams in which inguinal nipples associated with mammary glands existed.

It may be urged that although such a functional explanation is a plausible one for accounting for the mammary development of the Primates, yet it might in reality be some more obscure but inherent peculiarity of this stock to develop mammæ in the pectoral region; that the perfection of the human breast was surely more than the mere outcome of the convenience of some lowly Primate compelled to suckle its offspring amidst the branches of a tree.

Any doubts are, I think, dispelled by turning to other arboreal animals which are not usually admitted to be near relations of the Primate stock. Assuming, as we are entitled to do by all classifications accepted by modern zoologists, that the Edentata have no very intimate affinities with the Primates, then it must be an example of the development of similar anatomical adaptations to meet similar functional necessities that results in the typical mammary condition of the Sloths and their allies.

In these Edentates all the phases which we have followed in the Primate stock are displayed to perfection; the animals have become arboreal; the family has become reduced; and while some species possess both inguinal and pectoral mammæ, in others (the most purely arboreal forms) the inguinal nipples are lost and only a strikingly Primate pair of pectoral mammæ persists.

Another animal whose mammary condition needs mention here, though its zoological position will need discussion in another place, is the anomalous creature (*Galeopithecus*) sometimes known as the "Flying Lemur." The solitary offspring of *Galeopithecus* clings to its mother as do the young of Lemurs and Bats, and in this type again a pair of large pendulous mammary glands is situated upon the sides of the chest.

Possible Tendency to Unilateral Mammary Development.

We have followed the steps by which a reduction of the family leads to a reduction of the mammary series, and we have noted the process by which nursing in the arms led to the selection of the pectoral pair as the permanent human mammary glands. It is easy to understand that since the primitive mammary lines are bilaterally symmetrical structures, symmetrical mammæ will persist even when the production of only one offspring at a birth is the established rule. But it is also natural to ask if long continuance of this state of things may not tend to a unilateral mammary development; if the long-established habit of suckling only one offspring may not tend to the development of only one functioning breast.

From what we know of the laws of symmetry in the animal body it does not at first sight seem likely that any such tendency should be manifested. None of the Lemurs, Monkeys, or Anthropoid Apes show, so far as I know, any tendency to asymmetrical development of the mammæ; but the fact has been known to artists, physicians, and anatomists from the very earliest times that in the human female the left breast tends to be somewhat larger than the right. This fact is noticed time and again throughout the literature. Here we have a possible human tendency in mammary development; and again this tendency is the outcome of pure convenience in nursing.

Man has distinguished himself from all the other Primates in the almost universal preference for the specialised use of his right hand. The Primates lower than Man know no distinction in the use of right or left; Man alone shows a preference to perform specialised movements with one hand rather than the other. It is a matter of indifference to a monkey if the infant be carried on the left arm or on the right, and it is accordingly suckled indifferently at either breast. The majority of women, however, prefer to nurse the baby upon the left arm with its head towards the left breast, the right arm being free to perform other duties. This preference for suckling the infant at the left breast is manifested in women apart from any question of race or racial habit, and must be regarded as an outcome of the human tendency to asymmetrical specialisation in the use of the fore limbs.

One other factor has come into operation here, and this is the increasing separation of the mammary glands in the human as contrasted with the monkey type. This separation is brought about mainly by the widening of the chest, which is itself doubtless an outcome of the more upright posture of Man. In some Monkeys the breasts are so near together that the young of *Cercopithecus lalandii* has been seen to suckle from both nipples at once. This is, of course, impossible with the human type of chest and mammary gland; it must be one breast or the other, and selection is favouring the left breast.

THE INTERNAL GENITALIA.

As for the internal genitalia there can be no doubt that the arboreal habit has brought about the greatest changes. We have already seen that with regard to the lower segment of the female genital tract it is possible that the tree-climbing habit has left its mark very clearly indeed. We have noted that the length of this portion of the tract varies with the extent of the ventral pelvic symphysis, and that with the splaying out of the symphysis the tract becomes reduced in length. In this way the urogenital sinus has become progressively shortened until in the human female it is altogether absent; the long common chamber which exists with an ischio-pubic symphysis being opened out, as it were, by the splaying aside of the ischiatic rami. Hand in hand with this we have noted a progressive reduction of the male copulatory organ, and the development of this organ according to a very special type.

With regard to the upper portion of the internal genital tract of the female I am convinced that the reduction of the family consequent upon the arboreal habit has produced the very greatest changes. These changes are worthy of consideration, for to my mind we need some readjustment in our ideas concerning the progress of the evolution that has resulted in the production of the essentially human type of uterus.

It is possible for the student of pure human embryology to press his views too far; and in the explanation of many human anomalies I think it is probable that too much weight has been attached to mere mechanical interpretations of phases described as occurring in such human embryos as have been recorded in a series of different stages. To be properly interpreted ontogeny must be checked at every turn by phylogeny, and the mere structural study of sections and models should be controlled throughout by some appreciation of the physiological need of the developing animal for the special type of development of individual organs and systems.

It is, to my mind, essential in the study of the development of the human internal genitalia to keep constantly in view the fact that the chief modification has been imposed by the arboreal habit, and is an adaptation for procuring a system which shall accommodate only a single offspring during its pre-natal stages. The evolution of the uterus from the so-called "low mammalian" to the so-called "high mammalian" stage is merely a process by which a system designed for the reception of a large number of embryos is given up, and a system is evolved which is adapted solely for the needs of a single embryo. The differences between the processes as I shall describe them and those usually described may not seem great in detail, but the difference in functional conception of the evolution is considerable.

The Development of the Uterus.

I need not remind you that we generally assume that, from a condition of completely separated Müllerian ducts, evolution proceeds by stages of a partial fusion over a greater part of their extent; that whereas a lower Mammal has a large unfused portion—represented by the uterine cornua—these cornua have been fused and coalesced completely in the corpus uteri of Man. Such a theory is apparently supported by a whole series of anomalies which are well known to occur in the development of the human uterus. This conception might be summed up by saying that in Man the whole of the Müllerian ducts are fused into a common chamber, with the exception of that portion which forms the Falloppian tubes; and that the human uterus represents the coalesced uterine cornua of the lower animals. Such a conception has an initial inherent improbability, since the aim of evolution in producing the human type of uterus has not been to make a large median chamber out of two previously large bilateral chambers, but rather has been to perfect a single small chamber destined to accommodate a single offspring. The generally accepted explanation of the evolution of the Müllerian ducts is, to my mind, an example of embryology run riot for want of the proper controlling study of phylogeny.

Far from the development having taken place by the retention and fusion of the largest segments of the Müllerian ducts, it has taken place by an absolute reduction of a portion of the duct; for that portion of them which forms the uterine cornua of lower animals has, I believe, disappeared in man. The portion of the duct which forms the uterine cornua is destined to be the bilateral nidus of numerous offspring in the lower animals; this portion shrinks with the reduction of the family; it disappears when it is the established rule for the family to be reduced to a single offspring.

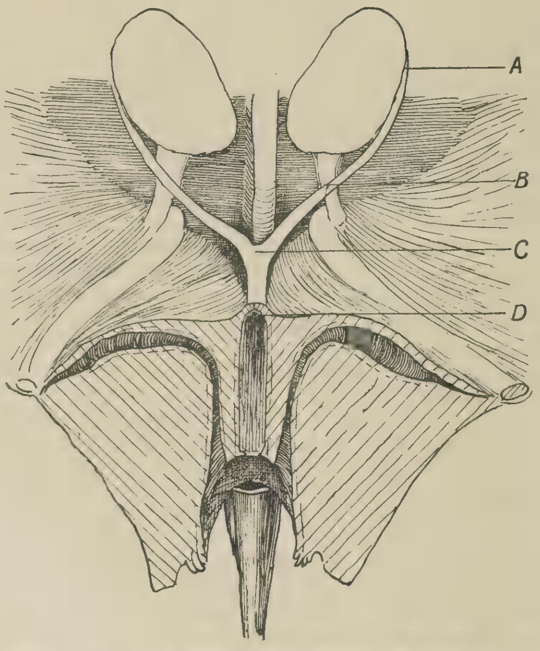
Quite apart from any study of embryology its reduction is strikingly displayed in the mammalian series. It is only necessary to contrast the uterine cornua of the large-littered pig with those of the mare to see that far from a median fusion of the cornua taking place to form a corpus uteri, it is the uterine cornua that are themselves dwindling in response to the diminished demands for the accommodation of multiple embryos.

Phases of Uterine Development in the Embryo.

Turning to the actual phases in the developing embryo, I think the process is made abundantly clear; and I imagine that the human uterus represents the caudal, median, fused portion of the Müllerian ducts such as is present in most lower Mammals, but that the uterine cornua are wanting in man. It is not that they are fused into the common chamber of the median uterus of man, but that they have disappeared in the process of development.

In the early stages of the Müllerian ducts all embryologists recognise three well-marked portions; the first, which lies in the long axis of the body and stretches from the cephalic end of the tube, at the ostium abdominale, to the gubernacular strand; the second, which is transverse to the long axis of the body and stretches medially from the gubernacular strand to the mid-line where it enters the genital cord; and the third, which is again in the long axis of the body and lies in the genital cord. (See Fig. 5.)

FIG. 5.



The female genital ducts of a fœtal mare. A–B, Falloppian tube segment. B, Gubernacular strand. B–C, Cornuate segment. C–D, Uterine or genital cord segment.

The fate of these three parts is easily followed. The first part forms the Falloppian tube; the second the uterine cornu; and the third (in which alone fusion ever takes place) the corpus uteri. The first two portions are suspended in their own bilateral mesenteries, and these portions do not fuse in any animal; the third portions are incorporated in a common mesentery, which is part of the genital cord, and these portions fuse in most (but not all) Mammals. The gubernaculum in the female persists as the round, or uterine, ligament of the ovary, and as the round ligament of the uterus. The first portion is therefore all that part of the Müllerian duct which is cephalic to the crossing of this strand; the wide-bored and thick-walled Falloppian tube of Man, or the narrow, thin-walled, and tortuous Falloppian tube of the lower animals.

It is sometimes assumed, even to-day, that the human Falloppian tubes are the representatives of the cornua of lower animals, and that the abnormal human tubal pregnancy is in some way a reversion to the condition of normal pregnancy in the uterine horns. Many of the older anatomists considered that the human Falloppian tubes were the homologues of the cornua of lower animals; Gerardus Blasius (d. 1684) makes use of this homology throughout his works on comparative anatomy. But it was recognised early that there were essential differences between the two structures, for Harvey says: "In a woman, as we have said, the two Trumpets near the process of the neck of the womb, which are perforated into the cavity thereof, are not commonly reputed proportionable to the Horns, but are conceited by some anatomists to be Vasa spermatica; by others Spiramenta uteri; by a third sort Vasa semen deferentia aut reservantia." But Harvey himself would have none of these ideas, and he lays it down as his opinion of the Falloppian tubes that "in truth they are answerable to the Horns of the womb of other animals."

The second portion stretches from the round ligament to the sides of the corpus uteri—this is the uterine cornua of the lower animals, but in man it is either altogether absent, or, if present at all, is represented by the so-called "interstitial portion" of the tubes. The third portion forms an inconspicuous median uterine chamber in most lower Mammals and constitutes the uterus of man.

The second, or intermediate, portion of the tubes —i.e., that part running primitively in the transverse axis of the body—is at first quite long in the human embryo. In the 19·4 mm. embryo the condition is similar to that seen in the lower animals which possess long uterine cornua; from the point of crossing of the gubernacular strand a considerable length of the human embryonic duct is taken up in the passage towards the middle line. In older embryos this portion appears relatively less and less developed. Its growth seems to cease altogether, while the portions upon either side of this stationary interval enlarge considerably. In this way that point on the tube to which the gubernacular strand adheres in its crossing alters its position relatively to the extremities of the tube; and we have only to look at the different courses taken by the gubernacular strand in the two main types of uterus, and in the intermediate forms which link them, to gain some idea of the relative degree to which the different portions of the tube develop in these types. With elongation of the second—or cornuate—portion of the Müllerian ducts the round-ligament attachment becomes moved in an upward and outward direction as the tube between it and the genital cord increases in length. (See Fig. 6.) On the other hand, with shrinking of this cornuate portion the point of attachment becomes dragged nearer and nearer to the genital cord, so that a sharp angle is developed between the portion running from the ovary to the tube, and the portion running from the tube towards the inguinal region. (See Fig. 7.) With further shrinking of the cornuate portion this angle becomes more marked until, with the final atrophy of the cornua, the gubernacular attachment is dragged in to the sides of the genital-cord portion, and blends with the musculature of the wall of the median uterine chamber. Such a condition is seen in the human uterus.

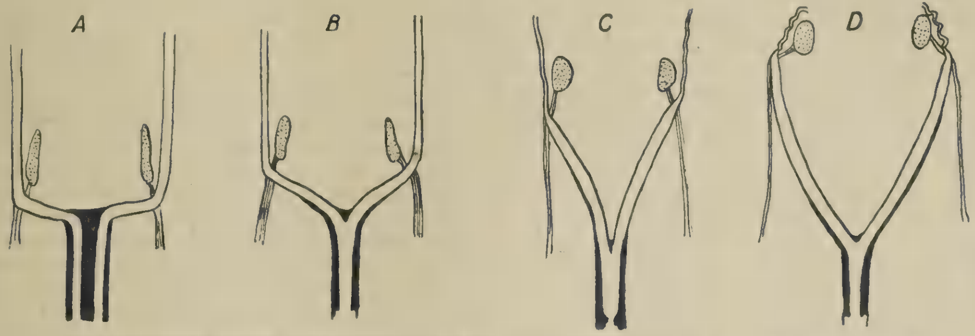
Stages of Uterine Evolution.

These stages of uterine development are all seen in members of the stock with which we are most concerned. Among the Insectivora Cloacaperta the uterine cornua constitute two entirely distinct chambers, there being no fusion even in the genital-cord portion, but in other members of the order the long cornua are united in the genital cord to form a small uterine body. The condition seen in the Tupaiadae (*Tupaia ferruginea*) is of interest. The Falloppian-tube segment is short, and although not markedly tortuous is of very narrow bore; the uterine cornua are long and capacious, but the corpus uteri is well marked and is conspicuously delimited by a well-marked os uteri leading into a vagina and urogenital sinus.

Among the lower Lemurs some extraordinary reversions to a low type of the Insectivora are displayed; but these reversions for the most part involve only the lower portion of the genital tract, and the uterus shows a steady advance (or rather adaptation to a single offspring) upon the stage seen in Tupaia. Indeed, no better summing-up of the general characters of the lemurine uterus could be given than that furnished by John Hunter in his description of the Lemur, which he terms the "Mongoose or Mocock." "The uterus," he says, "is between that of a monkey and of a common quadruped; or is what may be called the first stage towards the quadruped's or double-horned uterus." Such a condition may be illustrated by an examination of the internal genitalia of *Tarsius spectrum*. In this animal the Falloppian-tube segment is of narrow bore and slightly tortuous; the uterine cornua are comparatively short and thick, while the uterine body is well developed and is distinctly marked off from the vagina by an os uteri.

The next stage of development of the lemurine uterus may again be recorded in the words of Hunter, for in speaking of a lemur's uterus in which reduction of the horns has gone still further, he likens its outline to that of "the heart as it is painted upon cards." In the monkeys the reduction is still more complete, and it is impossible to refrain from quoting again, this time from Owen, who, describing the uterus of Baboons and Macacques, says that the angles of the fundus are slightly produced "like a last indication of cornua." This is indeed the last indication of cornua in the Primate stock, for the anthropoid condition is similar to that of Man.

FIG. 6.



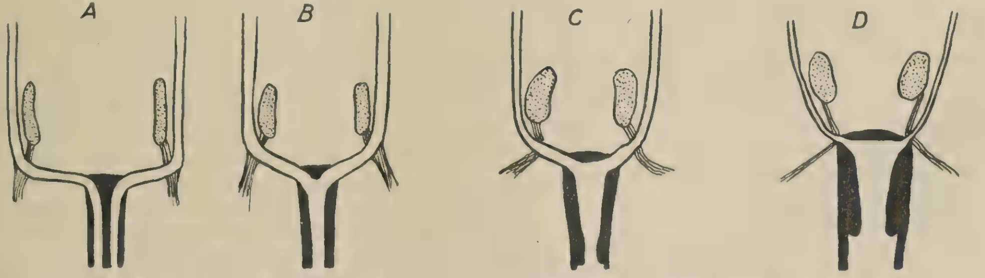
Four diagrammatic stages in the development of the "cornuate" or multiple pregnancy type of uterus.

Uterine Evolution in Bats and Edentata.

In examining the mammary evolution, we saw that collateral evidence could be derived from a study of the Bats (which I am considering as an offshoot of this line) and certain of the Edentates. The same interest is attached to the uterine conditions found within the limits of these two same orders.

In the various families of Bats this uterine evolution is extremely well displayed. Among the Megachiroptera (fruit-eating bats) the uterine cornua may be entirely separate, no fusion having taken place in the genital-cord segment, and separate "uteri" are present. This condition is seen in *Cynonycteris* (*Xantharpyia*), *Hypsignathous*, and *Epomophorus*; but in some other genera there is a fusion in the genital-cord segment and a small corpus uteri is present. In the Microchiroptera (for the most part insect-eating bats) the most primitive condition of the Megachiroptera is again found in *Taphozous melanopogon*, which has entirely separated cornua. In *Rhynchonycteris*, *Saccopterix*, and *Enballonura* the cornua are still large, but the genital-cord portion is represented by

FIG. 7.



Four diagrammatic stages in the development of the simple or single pregnancy type of uterus.

a small corpus uteri. In *Nyctinornus*, *Nycterides*, and *Vespertilio* the uterine cornua are diminishing and the corpus uteri is more conspicuous. And the process culminates in *Phyllostomatidæ*, in which the uterus is of a simple human type possessing no uterine cornua.

Among the Edentata the uterine evolution is still more interesting, for associated with certain features in the internal genitalia which we must certainly consider as zoologically "low" are uterine features which are distinctly advanced, or, as we should say here, associated with the arboreal habit of producing a single offspring. Undoubted reversions to a primitive Insectivorous type are seen in the lower portions of the genital tract, but associated with this "low" condition is a uterus that can only be described as human in type. In certain Edentata the uterine cornua have disappeared, not by fusion in a high type of animal, but because the cornua are not needed to accommodate numerous offspring.

Anomalous Development of the Uterus.

It will possibly be objected that even if this picture of the development of the uterus be supported by phylogeny, and is an apparently justifiable interpretation of the stages recorded in ontogeny, nevertheless the well-known human anomalies support the orthodox explanation so thoroughly that it is essential that any other attempted interpretation must explain them equally well. To my mind the picture I have attempted to draw of the evolution of the Müllerian ducts furnishes a better explanation of the human anomalies than does the generally accepted theory.

The human bicornuate uterus I regard, not as a malformation in which the Müllerian ducts have failed to fuse, but as an arrested stage—a reversion, if the term be preferred—by which the internal genitalia fail to achieve their full development in the atrophy of the normally temporary cornuate portion. A rudimentary, or undeveloped, uterus will be arrested in some earlier phase, a stage represented, not necessarily by non-fusion, but by ill development of the uterine body and persistence of the cornua. That portion within the genital cord which undergoes a fusion, phylogenetic and ontogenetic, may exhibit varying stages of incompleteness of fusion, and so varying types of septate uterus or double uterus may result. Failures of fusion occur in the third, genital cord, or uterine segment; failures of retrogression occur in the second or cornuate portion; and both conditions are the outcome of arrests of normal development.

CONSIDERATION OF OTHER POINTS.

One or two points left unconcluded need some explanation. I have alluded to the Marsupial genus Phascologale in connexion with nest-building. The Marsupial stock is so far removed from the animals with which I am especially dealing that any detailed discussion of them would be out of place here. I need not point out, however, that I am putting forth no new or original thought in mentioning that the marsupial pouch itself is possibly an early and only partially successful solution of the problem of dealing with a family in a stock which is said to be primitively arboreal.

Again I have made more than one reference to the Chiroptera and to Galeopithecus. These forms I regard as offshoots from the stock which we have had under review. Offshoots which in pre-Eocene times had made a thorough conquest of the branches, but which had been over enterprising, and had, in learning to glide and to fly, lost that very emancipation of the fore limb which had carried them so far and permitted them to make their fatal experiment.

I am aware that this study does not warrant wide-reaching conclusions, and yet it has its significance in the study of human origins. Since in this system we see that arboreal life has brought about so much that we regard as "human" (and in other systems it is even more striking), should we find anything very incongruous in the blending of a very large number of typically "human" characters in a form which is still a very primitively arboreal "animal"?

THE ORIGIN OF HUMAN ATTRIBUTES.

Leave for a moment the train of thought that we have been following. Turn back in your minds to the works of the pre-Darwinian period. Bulky volumes will occur to you, volumes crammed with eulogistic descriptions of Man and all his attributes. Whole shelves of our libraries are devoted to such works, and there is no end to the written plaudits of the perfection of human characteristics.

The nobility of poise, the charm of proportion, and the general distinct, and unanimal, aloofness of the human body are described with unstinting appreciation. The special attributes of the human mind are paraded, and the realities of family love, the social life, and the glorious culmination in unselfishness and lofty thought are emphasised to point the intellectual separation of Man from the rest of the animal world. The whole sequence of this trend of thought and all that it implied will readily occur to you.

Over a wide interval of upheaval, chaos, and extremeness we will pass to the period of a scientific yesterday. The work of the morphologists is accomplished. Man is a perfected, but in many ways a primitive, animal. He has outclassed his Mammalian competitors, and become distinct from them in many bodily and mental changes. The distinctive poise of Man remains in the newer conception of these changes, even if the praise of human bodily grace and proportions is left to a past generation; and the assumption of the upright posture is the key to the solution of the problem of the origin of human attributes. Man the upright animal is the dominant note of modern human morphology.

It is a step backward from Man the upright to Man the tree-climbing, but it is a step which we must take in attempting to learn the origin of human specialisation. It was among the branches that necessity determined and opportunity perfected the special adaptations of human bodily and mental characters.

I have confined myself to a very limited study of a single system; but every system and every part of man's body tell plainly the same story. Even within the limits of the system whose evolution we have been following, I think it is possible to see that some of the peculiarly human psychology, which has been the subject of so much admiration from moralists and philosophers; some of the perfections of the human female figure lauded by artists and poets; and some of the characters of internal structures exploited by the morphologist, were impressed upon the animal body by the schooling of arboreal life.

[Towards the cost of some of the material used in this investigation assistance has been afforded by the Dixon grant of the University of London.]

PULSUS ALTERNANS IN SOME OF ITS CLINICAL ASPECTS.[1]

BY C. O. HAWTHORNE, M.D. GLASG.,
F.R.F.P. & S. GLASG.,
PHYSICIAN TO THE HAMPSTEAD AND NORTH-WEST LONDON HOSPITAL AND TO THE ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.

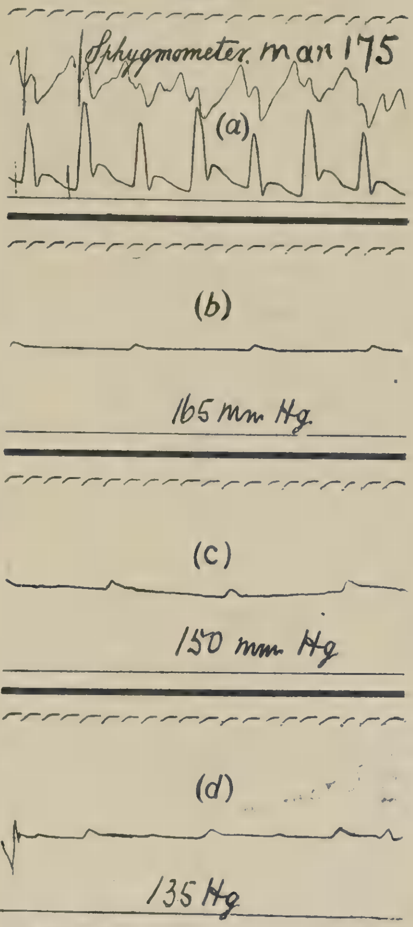
THIS communication deals with pulsus alternans in three different relations. The first of these is the bearing of pulsus alternans upon so-called blood-pressure records; the second is concerned with the clinical detection of an alternating pulse; and the third has reference to the influence of this form of pulse on prognosis.

Pulsus Alternans and the Sphygmometer.

When the sphygmometer is applied to a person in whom the arterial pulse has a normal and regular rhythm it is assumed that all the pulse waves are of equal force, and that the sphygmometer pressure necessary to suppress a selected series of radial beats is the exact measure, neither more nor less, of each individual beat. The measurement thus obtained is commonly quoted as the blood pressure or sometimes as the maximum blood pressure. As this external or sphygmometer pressure neutralises all the pulse waves during the selected period of observation, and as all the waves are assumed to be of equal force, the sphygmometer figure is accepted as an index of the force of each or any individual wave. Obviously this position must be modified in the case of pulsus alternans, for here the individual pulse waves are not of equal but of unequal force. Therefore a sphygmometer pressure necessary to suppress completely a series of such waves, that is, a pressure sufficient to neutralise the more forcible, must be excessive in respect to the less forcible. Hence if the sphygmometer measurement as ordinarily obtained is a record of the blood pressure, such a record in pulsus alternans must be incorrect in reference to 50 per cent. of the pulse beats. The figure which is true for the stronger waves is an exaggeration in relation to the weaker, just as the pressure needed to neutralise the less forcible waves would be deficient as a measure of the more forcible. In other words, the blood-pressure measurement as displayed by the sphygmometer must, in the case of pulsus alternans, be either a double one or an inaccurate one. If there is presented one figure representing the pressure associated with the more energetic pulse beat, and another figure for the pressure of the less energetic, the position may be harmonised with the values which the sphygmometer professes; but short of this there is no safety—to suppress all the beats is to err in the direction of excess; to suppress only the weaker ones is to err in the direction of defect.

The situation just defined is exactly illustrated in Fig. 1. The first tracing (*a*) is the ordinary sphygmographic picture of pulsus alternans, and the sphygmometer pressure necessary to suppress all the radial beats is attained when the mercurial column reaches a height of 175 mm. In the language of the hour, therefore, the patient has a blood pressure represented by the figure 175. If now the sphygmometer pressure is lowered to 165, some of the pulse waves come through (*b*), while others are suppressed; and it is obvious that the former are the alternate strong beats and that the missing waves are the alternate weaker ones. This experience is repeated when the sphygmometer pressure is further reduced to 150 (*c*), and it is not until the pressure has fallen to 135 that the alternate weaker beats are seen in the sphygmogram (*d*). If then the usual sphygmometer method were applied to this case the blood pressure would be recorded as 175, a figure which is manifestly inaccurate, as judged by the sphygmometer's own showing, in relation to one-half of any period to which the record may be held to apply. The only alternative would be to register the blood pressure as 175 at one moment and as, say, 140 at the next succeeding moment, and to intimate that this alternation is indefinitely repeated. Now it can hardly be proposed that such alternation of blood pressure can be due to a rhythmical alternate contraction and dilation of the peripheral arterioles. Hence the difference in sphygmometer measurement between the alternate strong and weak beats must be due solely to a difference in the degree of cardiac force. But if this is true of differing pulse beats and differing sphygmometer measurements in one and the same individual, it must surely be true also of differing pulse beats and differing sphygmometer measurements in different individuals. The measurements vary, or may vary, as expressing different degrees of cardiac force—a display which, however interesting, is certainly not a complete picture of the blood pressure. In general terms, therefore, while the maximum sphygmometer reading as usually taken may afford an approximate intimation of the degree of force with which the

FIG. 1.



---

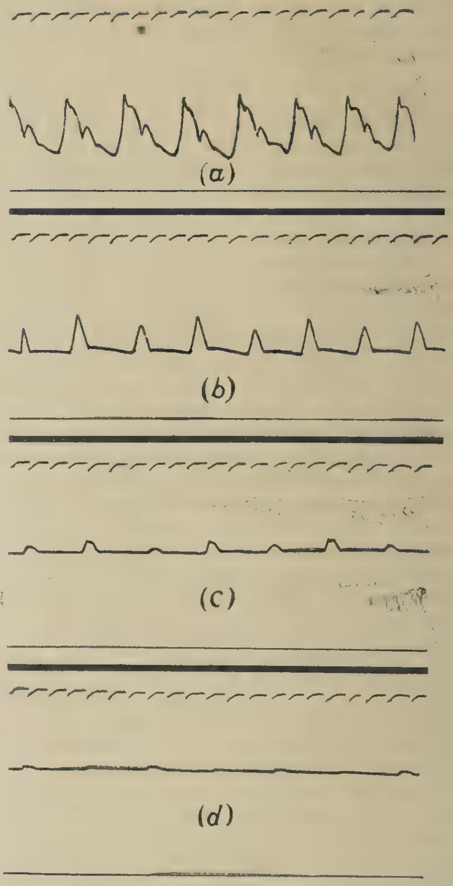
[1] The substance of this paper was communicated to the Association of Physicians of Great Britain and Ireland at the Cambridge Meeting.

systole of the left ventricle arrives at the brachial artery, it is far indeed from offering a comprehensive presentation of the state of the blood pressure. This is not to challenge the clinical value of the sphygmometer, at least within certain limits, but it is to advance a basis for the claim that records obtained by this apparatus ought to be expressed, not in terms of blood pressure but rather in terms of sphygmometric measurement. There are other considerations which support this claim. Thus, while the sphygmometer reading is a fact, its interpretation as blood pressure is an inference, and descriptive scientific terms ought to announce facts and ought not to enclose speculations or opinions; again, whatever contribution may be made to the sphygmometer record by the pressure of the blood, something—admittedly a very uncertain something—is contributed by the resistance of the arterial wall and perhaps also by the resistance of other tissues, so that, as a matter of fact, the reading is not purely a record of blood pressure; and further, stated at its highest, the claim of the sphygmometer, at least in its maximum record, is limited to the ability to present a single aspect of blood pressure—namely, the height to which such pressure rises during a period of time of uncertain, undefined, and therefore of possibly varying duration. These considerations certainly suggest the need for some care in the phrasing of sphygmometer records, and the argument now advanced is that a study of pulsus alternans in relation to such records adds strength to the suggestion that they should be recited in terms of sphygmometric measurement and not in terms of blood pressure.

The Detection of Pulsus Alternans.

The second proposition which I wish to advance is a more practical one. It is that a pulsus alternans which may escape the finger, and the stethoscope, and perhaps also the pulse tracing may be rendered evident and even conspicuous by the combined use of the sphygmometer and the sphygmograph. This is illustrated in Fig. 2. The radial pulse of the patient from whom these tracings were taken was certainly not suspected by the finger to have the characters of pulsus alternans, and, as seen in the first of the tracings (*a*), no such suspicion is justified by the sphygmogram. Yet if, while a radial tracing is being taken, more or less pressure is exercised on the brachial artery, the distinctive features of pulsus alternans come out very conspicuously. The difference between the height of the alternate waves is most decided when the sphygmometer pressure is at a moderate level (*b*), it is somewhat less decided as the pressure is increased (*c*), but it can still be appreciated even when the pressure is carried near to the obliterating point (*d*). The same truth is illustrated in Fig. 3, where the upper tracing was taken under ordinary conditions and each of the two lower ones while the brachial artery was subjected to a greater or less degree of pressure by means of the sphygmometer armlet. In this instance, however, it must be admitted that the original sphygmogram does offer to careful examination some hints of the presence of pulsus alternans. First, there will be noticed a slight difference in the height of the alternate waves; and, secondly, each of the less prominent waves is also less sustained, as is shown by the relatively less conspicuous "shoulder" or tidal wave. To judge from this tracing, therefore, the existence of pulsus alternans means an alternation not only in the force but also in the duration of the alternate cardiac systoles, and such an observation is the more interesting in view of the statement that no such variation can be discovered by the electrocardiograph.[2] The point here of importance, however, is that a condition of pulsus alternans which might well have escaped detection by the ordinary methods was readily made evident when a radial tracing was taken under the influence of pressure applied to the brachial artery through the armlet of the sphygmometer.[3]

FIG. 2.



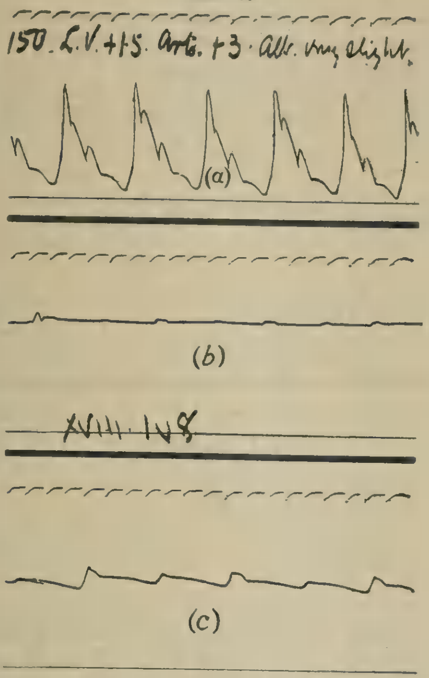
When the observations just described had once attracted attention it seemed necessary to test, almost as a matter of routine, the effect produced on the radial pulse tracing by pressure applied to the brachial artery. Without such test it appears impossible to be sure that any pulse, however regular and normal to the ordinary methods, may not perchance be, and as it were in a concealed fashion, an example of pulsus alternans. When this is done it is surprising to find how frequently a pulse which seems to be composed of equal waves, the products presumably of equally forcible cardiac systoles, offers suggestions that the waves are not really equal, and that the cardiac systoles which produce them are therefore not equal. In Fig. 4 is seen a sphygmogram of which the constituent waves, all of them, have apparently an equal force and an equal duration. After the tracing had been taken the paper was removed and was again passed through the sphygmograph, while, at the same time, the sphygmometer armlet was tightened around the upper arm to a degree sufficient to suppress the radial pulse. In this way the upper line of the tracing was drawn, and it shows that, though most of the pulsations are suppressed, every now and then a wave effects its escape past the sphygmometer armlet and is registered as a radial movement. Similarly in Fig. 5 the ordinary sphygmogram presents a series of waves of which every one appears to be identical with its fellows, yet when pressure is applied to the brachial artery the beats come through not in equal but in unequal excursion (*b*), and even when the pressure is urged to what appears to be the obliterating point there is still an occasional radial movement (*c*). In a word, these observations appear to show that even when the pulse waves as exhibited in a sphygmogram may seem to be of equal force and value, some of them, when tested, may, at least in individual instances, overcome a pressure to which others are obliged to yield; that, in short, the appearance of sphygmographic wave equality is not a final and conclusive proof of essential wave equality.

---

[2] Diseases of the Heart, Dr. James Mackenzie, third edition, p. 258.

[3] Since writing this paper I have learned that an observation similar to that recorded above has been made by Dr. Louis Gallavardin, of Lyons, who, in an article entitled "Pouls Alternant et Cœur Alternant," published in *Le Journal Médicale Français*, Feb. 15th, 1913, writes: "La seconde conclusion est que l'on aura intérêt à *aider le doigt explorant la radiale, de la compression de l'humérale* au moyen d'une manchette brachiale pneumatique ou plus simplement d'un des doigts de l'autre main. On arrivera ainsi à mettre en évidence des alternances que la palpation radiale simple aurait sûrement laissé échapper. ...... Il y a ...... une alternance *latente*, insensible au doigt, invisible même sur les tracés sphygmographiques, et que la méthode sphygmomanométrique et l'exploration bidigitale parviennent seules à mettre en lumière."

FIG. 3.



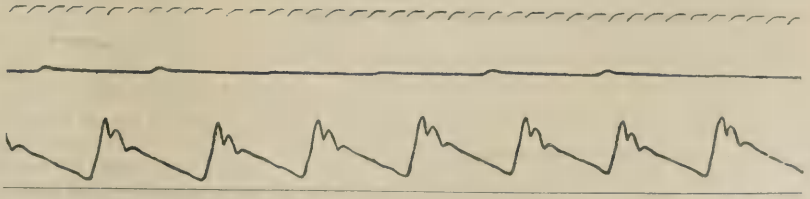
Is it, then, necessary to admit that pulse waves which appear to be equal may be the products not of equal but of unequal cardiac systoles? *A priori* this question would certainly be answered in the negative. Yet some explanation of the above facts must be found, and it is by no means certain that the *a priori* conclusion is the correct one. It is beyond question that the "escaping beats," as they may be called, of Figs. 4 and 5 are not due to a gradual fall of pressure in the sphygmometer, for were this the case they would, when once established, continue to appear, and presumably in an increasing measure; whereas, as the tracings show, the arrival of one or more of the "beats" may be followed by a more or less prolonged period of complete suppression. Nor would the suggestion of a falling sphygmometer pressure explain the irregularly unequal waves of Fig. 5 *b*.

Another explanation of the tracings (Figs. 4 and 5) now under discussion might be that the radial pulse movement varies in consequence of varying degrees of pressure exerted on the brachial artery as a result of involuntary muscular contractions in the upper arm. To exclude this proposal with complete confidence is not easy, and it is perhaps equally difficult to affirm it. Were it true there ought to be with each "escaping" beat a fall in the sphygmometer index—assuming the instrument to be sufficiently delicate for such a record—and personally I have not been able to detect any such happening.

At first sight it seems an extravagant suggestion to say that the "escaping" beats in Fig. 4, or the more marked waves of Fig. 5 *b*, are due to exceptionally vigorous cardiac systoles, for such a suggestion, in view of the corresponding and apparently normal sphygmograms, would involve the proposition that cardiac systoles which, measured by all the usual clinical methods, appear to be of equal force and value are really of unequal force and value. Yet when we find that this conclusion is necessitated in certain cases of pulsus alternans (Fig. 2), may it not be true also in instances in which the differences between cardiac systoles of apparently equal merit occur irregularly rather than in an alternating series? If inequality has to be admitted in the systoles responsible for the apparently equal waves of Fig. 2 *a*, how can we deny the possibility of inequality in the systoles of which the apparently equal waves of Fig. 4 are the product? All that is needed to bring the two tracings on to the same platform is to suggest that in one case (Fig. 2) the variation in the force of the systoles occurs with alternate contractions, while in the other case (Fig. 4) the variation is irregular and without apparent plan.

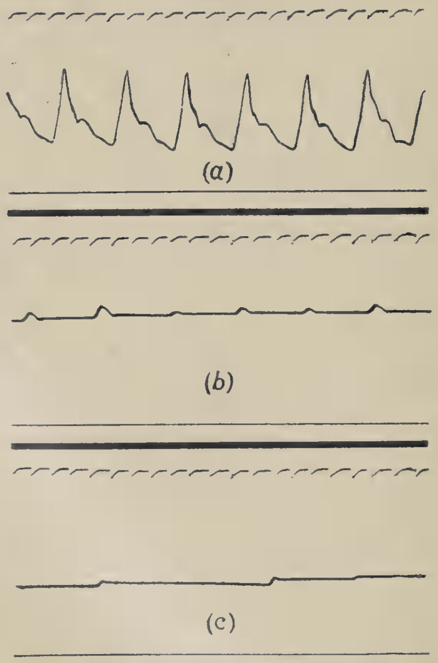
The conclusion just stated will appear less extravagant if it is recognised that the differences displayed in the apparently equal waves of certain sphygmograms when pressure is applied to the brachial artery may be differences which, in ordinary circumstances, are potential only, and that to expose them it is necessary to erect the special conditions which such brachial pressure implies. It is generally allowed that pulsus alternans, in the case of a heart predisposed to adopt this particular rhythm, may be excited or revealed by any circumstance which increases the degree of cardiac strain, and possibly obstruction of the brachial artery by the armlet of the sphygmometer may be such a circumstance. From this it

FIG. 4.



is no great advance to the suggestion that the same condition may perchance be sufficient to evoke a display of non-alternating variation in the force of the cardiac systoles when a tendency to such variation exists. In this way the two orders of events exhibited in the tracings which accompany this paper would be harmonised in principle, the only difference being that in the one group (Figs. 2 and 3) the armlet pressure reveals a tendency to an alternating variation in the force of the ventricular systoles, and in the other (Figs. 4 and 5) a tendency to an irregular (non-alternating) variation. Yet in each instance it remains true that these tendencies to an abnormal rhythm would not have been discovered unless, in addition to the usual methods of examination, the pulse had been tested while pressure was applied to the brachial artery. And this involves the admission that the apparently equal waves of a sphygmogram may arise from cardiac systoles which, if not unequal in the existing conditions, may at least be unequal in their capacity to deal with the circulatory position created by obstruction, partial or complete, of a medium-sized peripheral artery. Though the sphygmographic waves appear to be the products of ventricular systoles of identical value, a pulse-tracing taken while the brachial artery is subjected to pressure may show that such systoles are essentially unequal, at least in the sense that they vary in their ability to meet a new situation with one and the same measure of success.

FIG. 5.



(a)

(b)

(c)

Apart from the discussion, doubtless somewhat speculative, of the significance of such tracings as Figs. 4 and 5, the tracings have this practical interest, that they show how easy it may be for different observers in one and the same case to record different levels of sphygmometer measurement according as the observation is made at a point where one or more "escaping beats" pass the sphygmometer armlet, or, on the other hand, during a period when all the waves seem to be suppressed. Whether the tactile or the auditory method of estimate be employed, the presence of these "escaping" beats is certainly not very uncommon, judging at least from observations made on patients of whom probably the majority were the victims of cardio-vascular degeneration. In cases of this order such tracings as Figs. 4 and 5 may be noted at least every now and again.

Pulsus Alternans and Prognosis.

There is a general agreement among writers on the subject that pulsus alternans almost invariably carries a very alarming prognosis. When exceptions to so serious a rule occur it is of some importance that they be recorded. As it happens, I am able to quote a case in which the patient is still alive, and believes herself to be quite well, although so long as five years ago (Fig. 6 *a*), and on many occasions in the interval, her pulse has shown characteristic alternation. At the date of the first observation (1909) she was 22 years of age, and was found to present distinctive clinical evidences of chronic interstitial nephritis, including albuminuria, cardiac hypertrophy, a high sphygmometer reading, and extensive retinal changes. Yet she has continued to discharge her household duties as the wife of a poor man and the mother of three children, and she professes to-day to be quite well and free from all complaints other than occasional headaches. No doubt this sense of well-being is in some measure misleading, as the physical changes above described (other than the retinitis) still persist; on some occasions, too, the pulse tracing shows the features of pulsus alternans, whilst on others the tracing has the characters exhibited in Fig. 6 *b*. Allowing freely that the woman is not "cured" as she believes herself to be, there remains the fact that she is alive and active even though six years ago pulsus alternans in a quite decided form was part and parcel of her clinical state, and that it existed in association with the cardio-vascular changes which mark the progress of chronic interstitial nephritis. In view of the terms in which the prognostic significance of pulsus alternans is usually phrased such an experience is certainly noteworthy. The more serious the general rule the more welcome is it to find the possibility of exceptions.

Harley-street, W.

HOME OFFICE ORDER AND DEATHS IN BATHS.—The Home Office has issued an order that in the case of all deaths occurring in baths an expert pathologist shall be called in to make a thorough investigation of the circumstances and to give evidence at any subsequent inquest.

SOME ASPECTS OF THE CILIARY BODY IN HEALTH AND DISEASE.

BY H. PERCY DUNN, F.R.C.S. ENG.,
CONSULTING OPHTHALMIC SURGEON TO THE WEST LONDON HOSPITAL.

OF the structures composing the uveal tract the most important is the ciliary body. Herein it may be said that the soul of the eye resides. The ciliary body may be compared to the escapement mechanism of a watch. Just as the performance of a watch depends upon the protection of the delicate mechanism of its escapement, so does the nutrition of the eye depend upon the integrity of the ciliary body. In a watch the escapement forms the most delicate part of the movement. The pivots, for example, work in jewelled holes to lessen friction and diminish wear, and any disturbance of the accurate adjustment causes the watch to go irregularly or cease to go at all. Almost the same is the case with the ciliary body. Disturbance of its nutrition generally means impairment or arrest of the nutrition of the eye. While inflammatory conditions of other structures of the eye do not directly imperil the existence of the organ, inflammation of the ciliary body in more or less degree always does so. And the reason is not far to seek. The explanation lies in the special structure of the ciliary body and in the function it discharges. Anatomically, the outstanding features of its structure are its vascularity and sensory nerve-supply. As the blood organ of the eye it consists of a dense plexus of blood-vessels supported by connective tissue and arranged in the form of processes constituted from the inward folding of the various layers of the choroid. So, also, in similar density, is the distribution to the ciliary body of the sensory nerve-supply derived from the long and short ciliary nerves. The extreme sensory endowment thus provided is probably a special feature which Nature has been careful to arrange, in order that early warning may be given of the pathological dangers to which the ciliary body is exposed. By this means, in the case of an inflammatory attack the ciliary body is at once enabled to transmit a "S. O. S." call for therapeutic assistance. Useful in this regard as a symptom is the intense agony associated with an acute attack of primary glaucoma, indicating, as it does, the urgency of immediate relief. The pain in these cases is due to the vascular engorgement of the ciliary body, and to its compression against the unyielding sclera. For the same reason a primary iritis only becomes painful when the ciliary body is involved in the inflammation; an iritis, *per se*, is not painful, but when the attack is accompanied by pain, the eyeball is then found to be tender to palpation, showing the presence of cyclitis and the severity of the inflammation.

The next point which bears upon our theme is the function discharged by the ciliary body. It has already been observed that this function is mostly concerned in maintaining the nutrition of the eye. This is accomplished by ensuring a normal intra-ocular tension. The contour of the globe depends upon the two transparent media, the aqueous and the vitreous, and the ciliary body, by providing the fluid-supply, enables these media, under normal conditions, to preserve the tension required.

Incidentally, it may be noted that an interesting controversy has arisen in respect of the special means by which the intra-ocular fluid, represented by the aqueous, is derived from the ciliary body. In the first place, there are those who hold that the fluid is formed by filtration, and, secondly those who maintain that the fluid is manifestly a secretion. This diversity of view mainly prevails among the physiologists. Then the ophthalmic surgeons appear on the scene. They have a difference of opinion with the physiologists who favour the secretion theory. Since Collins, by an ingenious inquiry with bleached sections, demonstrated what he believed to be glandular bodies in the ciliary processes, attributing to them the secretory source of the aqueous, ophthalmic surgeons have generally accepted the revelation; but the physiologists, on the other hand, have shown no sympathy with this discovery. Their accepted view is that the aqueous is secreted entirely by the uveal epithelium covering the ciliary processes—curiously enough, this was practically the view propounded by Méry, so long ago as 1707. Moreover, it has been pointed out by Leber that the tubular invaginations of Collins have not the anatomical character of glands, having no secretory duct, no proper lumen, and no glandular epithelium.[1] In some recent correspondence which I have had with Professor Bainbridge upon this subject, he writes: "The view most commonly held, and which I share, is that the aqueous is formed by filtration through the ciliary processes." And so the matter, as indicated above, stands in the present day. The advocates of each view maintain their position. Possibly the controversy in the main may be reduced to an axiomatic statement—namely, that lymph is not a secretion, and the aqueous is not lymph. If lymph only were necessary for the supply of intra-ocular fluid, how is it that the protein content of the aqueous is negligible in comparison with that of lymph?

But the question of greater importance in this connexion is not whether the aqueous is a filtration or a secretion, but that its character varies, as the blood varies from which it is derived. Owing to its extreme vascularity the ciliary body is very responsive to blood changes. We see this in the irido-cyclitis of syphilis, of tubercle, of gonorrhœal rheumatism, of alveolar pyorrhœa, to mention some instances. In all these the aqueous undergoes a marked change in character, physically shown by a varying degree of turbidity. Turbidity of the aqueous means also a corresponding turbidity of the vitreous. Normal aqueous has been shown to be sterile. Again, aqueous is claimed to become toxic in cases of septic ulceration of the cornea, the toxin from the septic focus passing through the layers of the cornea, through Descemet's membrane, and so entering the anterior chamber. The effect of the toxin is to cause the aqueous to act as an irritant upon the tissues of the uveal tract, leading to the exudation of polymorphonuclear cells, which fall to the bottom of the anterior chamber, forming hypopyon. The aqueous is also toxic in irido-cyclitis of endogenous origin, and this explains the occasional presence of hypopyon associated with these inflammatory attacks.

The toxic condition of the blood, due to perverted metabolism, affects in varying degree the nutrition of the eye. Metabolic processes as a whole depend upon the controlling influence of the thyroid gland. In this regard two morbid entities represent the extremes of thyroid disturbance—hyper- and hypo-thyroidism respectively. On the one hand, "systemic goitre," as an American writer prefers to call exophthalmic goitre, and on the other myxœdema, in which atrophy of the gland is present. Between these two extremes lie diseases of metabolic origin of lesser magnitude, the signs of which are those of hypothyroidism. The simplest form, I believe, of this toxæmic influence of metabolic perversion is met with as an ocular manifestation. It has been customary to ascribe so-called "muscæ volitantes" to a physiological source. The physiological basis of their presence is attributed "to the persistence of portions of the framework of the fœtal vitreous" (Collins). The fact, notwithstanding, remains that this entoptical disturbance of the vision only becomes troublesome to those who for some reason at the time believe themselves to be suffering in health, for only on these occasions is it that complaint of "black specks" is made. At other times there is freedom from the trouble. Hepatic disturbance is the popular conception of the cause. The history of these cases suggests that "muscæ volitantes" is a pathological, rather than a physiological, sign. They indicate that some metabolic disturbance has ensued by which the aqueous has become defective in transparency or in some degree changed from its normal character. In one case a patient alleged to me that he was always troubled with muscæ volitantes at business on the day after attending a public dinner. He attributed the sign, which ceased to be noticeable after some hours, to the food taken being imperfectly digested. In the cases where muscæ volitantes remain persistent hypothyroidism in some degree may be inferred, for which thyroid treatment is indicated. So far as the eye is concerned the sign is of no import, but regarded as a systemic manifestation its recognition may prove of value to the patient.

---

[1] Norris and Oliver: System of Diseases of the Eye, vol. i., p. 198.

When we come to consider inflammatory states of the ciliary body there is in certain cases clear evidence of the evil influence of metabolic disturbance. In so-called serous irido-cyclitis, or more commonly, keratitis punctata, or, shortly, "K.P.," the signs of hypothyroidism are distinctly manifest in the patient. The etiology, nevertheless, of this disease has never been definitely determined. The disease is distinguished by a chronic passive inflammation of the uveal tract, accompanied by the deposition of "dotted opacities" upon Descemet's membrane, which assume a triangular outline, with the base downwards. These "dotted opacities" consist of "lymphocytes and plasma cells" derived from the uveal tract, exuded as the result of the toxæmic irritation of the tissues. The history in such cases is always typical. Apart from the ocular signs the patients complain of loss of appetite and flesh, of physical and mental depression, of coldness of the hands and feet, and of overwork, to the effect of which the signs are attributed. Thus these cases are met with mostly among women whose ordinary strength is unequal to the demands of their occupations. The metabolic origin of these signs, due to hypothyroidism, is proved by the rapid improvement which follows thyroid treatment. With 3 grains, twice daily, of thyroid extract even in the course of a week a noticeable change ensues. A marked feature is the early return of the appetite, and partly, no doubt, from this patients soon begin to increase in weight. In the course of a few weeks the irido-cyclitis has cleared up, the appetite has become vigorous, physical and mental alertness have become visible in movement and facial expression, and convalescence is practically established. One among many typical instances of the kind was in the case of a former West London Hospital nurse, who, while private nursing, fell under the ban of these symptoms through an excess of night duty. The value to her of thyroid treatment met with a response of appreciation which left no uncertainty in respect to the accuracy of her condition. A measure, it must be confessed, of fascination belongs to the therapeutic value of thyroid treatment. There is the rapidity of action which follows its use; there are its far-reaching effects, accomplished by means so apparently simple, as would probably have astounded the multi-drug prescribing physicians of old. In the case of many a poor overworn patient, depressed and ailing, unfitted for work, from whom the joy of life has temporarily passed, the extract of thyroid proves a veritable elixir of life. But while reaping the gratification which springs from the benefits it confers no doubt the patient wonders, with full reason, how so trivial a thing as a small tablet, neither drug nor chemical, should possess the power for good it displays. And so of the many great advances of modern medicine I believe the evolution of our knowledge of the protean effects of hypothyroidism and of its treatment by thyroid extract to be one, at least, of the greatest. What is true of the therapeutic value of thyroid extract in the treatment of keratitis punctata is equally true of that large class of cases of ulceration of the cornea among the poor, the cause of which is generally attributed to "debility." Among these are included the cases which in olden days would have been described as "strumous ophthalmia." Nowadays the term "strumous" has ceased to be officially recognised; persons, the victims of active tubercle, are now not strumous but tuberculous; persons who look "strumous" now emphasise the general signs of hypothyroidism, in more or less degree, and these signs vanish under thyroid treatment.

Attention may now be drawn to a further aspect from which metabolic toxæmia affecting the ciliary body may be considered. First, it may be said that the term "vicious circle" is applicable to cases of metabolic toxæmia. There is the primary stage, represented by auto-intoxication, arising as we may assume, in the intestines. To combat the toxæmia so-called, the thyroid gland, through its secretion, is called upon to make strenuous efforts under the influence of excessive stimulation. For a time these efforts are successful. Later on, however, the thyroid fails in its mission. Then follows the second stage—namely, hypothyroidism. With this begins a pervading uncontrolled toxæmia. Accompanying this, and dependent upon it, is the last stage—that of diminished resistance of the tissues, thus rendering them a prey to bacillary infection. The difficulty, however, of these cases lies in the absence, oftentimes, of any cause of the toxæmia and of the hypothyroidism which is present. In the case of "K. P." the signs of hypothyroidism are so well marked that the existence of some source of toxæmia is at once suspected. But while it is impossible to believe that any toxæmic condition could fail to depress the action of the thyroid, the fact remains that the hypothyroid effect is not always actively marked—for example, a case comes under observation of irido-cyclitis, the cause of which is due to alveolar pyorrhœa. Here the source of the toxæmia is evident. On the other hand, the hypothyroid effects are commonly but little noticeable, or even, it may be, are absent. In former days the toxæmic source of these cases was overlooked. They were classed under the generic name of "rheumatic," and rebellious to treatment they proved upon the basis of their rheumatic origin. The perversion of metabolism, however, which establishes an irido-cyclitis in alveolar pyorrhœa, is also responsible for the disease in other forms of auto-intoxication. Hence the term "rheumatic" now conveys no etiological significance beyond implying that the attack of irido-cyclitis is of toxæmic origin. There is held to be some association between these attacks and so-called gonorrhœal rheumatism, inasmuch as in such cases a common history is that of a previous gonorrhœal infection. But the term rheumatism suffixed to gonorrhœa is merely a term, and in these days might with advantage be improved upon. The signs of so-called gonorrhœal rheumatism may be symptomatic of rheumatism. But, on the other hand, these signs are probably due to a para-gonorrhœal toxin, as distinct from that present in a pure rheumatic attack, as is the toxin of tetanus from that of any other pathogenic organism.

The fact of the toxæmic origin of these cases being admitted, the assumption follows that a more or less degree of hypothyroidism is present which requires as the first line of systemic treatment the administration of thyroid extract. A striking instance of the efficacy of this method was in that of a man suffering from a third attack of so-called rheumatic irido-cyclitis. The signs were acute, the eye was intensely painful. Three grains of the extract were ordered twice daily. After taking the third tabloid all the pain ceased, and yet the severity of the pain was such as to indicate relief by leeching.

Metabolic toxæmia, I believe, bears closely upon another form of irido-cyclitis—namely, that associated with the acute parenchymatous keratitis of inherited syphilis. Congenital syphilis is a disease of very varying virulence. The many eccentricities which distinguish its mode of transmission find their counterpart in the varying intensity of its incidence. An infant may be grossly syphilitic at birth; then it commonly fails to survive. But while this represents the extreme effect of the hereditary transmission, on the other hand the stigmata of congenital syphilis may be so nebulously manifested as to escape notice. In these cases nothing may happen until later childhood. Then may come an attack of interstitial keratitis, which reveals the certainty of the taint. Moreover, this interstitial attack may be the only manifestation, an isolated symptom at the time, unaccompanied by any additional evidence of systemic infection. Of such cases I can recall instances which have come under my observation where deafness, disseminated choroiditis, gummata, and nodes, the common signs associated with an interstitial attack have each been absent.

The logical inference to be derived from these cases is that congenital syphilis can be at times a very benign disease, the presence of which is displayed only when some adventitious tissue environment renders its manifestations possible. The evidence of that environment is commonly shown in the children in whom acute parenchymatous keratitis develops. Frequently the general condition of the patients is more noticeable than the ocular signs of which they complain. These children are mostly wasted, pallid, feeble with malnutrition actively marked—objects of physical misery from every point of view. The stigmata of syphilis in active virulence are not here exhibited in the general condition of the patient. On the contrary, the general signs are those of metabolic toxæmia, of depressed vitality arising from hypothyroidism. As such they correspond to those to which attention has already been drawn in connexion with keratitis punctata. The view that the spirochæte becomes attenuated in virulence in the process of transmission is supported by the fact of its failure to impress upon its host the facial and other features which form the peculiar appanage of syphilitic inheritance. Whenever, therefore, these conditions prevail it may be concluded that except for the adventitious tissue environment represented by hypothyroidism, the spirochæte would be unable to exhibit the pathogenic influence which still remains to it. This assumption is borne out by clinical experience. The worst cases met with of interstitial keratitis are always those in which the signs of hypothyroidism are most pronounced. At this point some reference may be made to the widely divergent views which prevail of the nature of interstitial keratitis. By some authorities it is held that the disease is directly due to the action of the spirochæta pallida; by others that it is only, indirectly, a manifestation of syphilitic infection, and that it should be included among those of the para-syphilitic type. Elschnig believes that the disease is a degenerative one, due to disturbance of nutrition, arising from toxins circulating in the blood stream. My view, as will have been gathered from the reasons already expressed, closely accords with the latter, and it is in consequence of that view that for some years I have regarded cases of interstitial keratitis as not among those to be treated by antisyphilitic remedies. Upon this subject I may now add a few further remarks. Believing, as I do, that the pronounced objective signs of malnutrition indicate that the syphilitic manifestation is secondary to, and has only been rendered possible by, the metabolic toxæmia present, it seems entirely unscientific to treat these cases heroically by "606," and by leeching to relieve the photophobia. It may or may not be admitted that there is but little syphilis in these cases, but the fact nevertheless must be conceded that the disease is overshadowed by the evident malnutrition. Amid, therefore, the pervading diminished resistance of the tissues, the spirochæte is able to assert its presence, but in consequence of the depressed vitality the tissues are unable to respond, save feebly, to the therapeutic influence of antisyphilitic treatment. The persistent method of treating these cases, as if they were purely syphilitic, by heroic measures, has probably been accountable for the notorious repute they possess of requiring a prolonged period of treatment before convalescence is established. Thirty years ago it was commonly held that 18 months' treatment at least was requisite before cases of interstitial keratitis could be regarded as cured. This cheering information used to be imparted to the parent attending with her child for treatment. But it is true that the severity of the inflammation was much greater then than is now customary to be seen. The cornea was not infrequently wholly vascular, "salmon" colour in appearance.

The lines of treatment which I have followed for some years include beginning with 3-grain doses twice daily of thyroid extract, and locally fomentations and atropine. As the nutrition proceeds in improvement so the ocular signs diminish in severity. In a deplorably bad case of malnutrition, a case typical of the worst form of double interstitial keratitis, a child under this treatment was fat, strong, and well at the end of three months. And there the problem remains; if interstitial keratitis be purely and wholly a syphilitic lesion, how is it curable without antisyphilitic treatment? Impartial reasoning suggests that except for the tissue environment of pronounced diminished resistance the attenuated spirochæta pallida of a benign congenital transmission would fail to exert its pathogenic influence. The possibility of this view being correct throws emphasis again upon the value of recognising the vulnerability of the ciliary body—practically the blood organ of the eye—to metabolic disturbance. It emphasises, too, the therapeutic advantages to be gained by combating such toxæmic manifestations by thyroid treatment. Moreover, in this connexion the reflection inculcated in the following quotation from a paper by Hertoghe, of Antwerp, applies with force to ophthalmic surgeons—namely, "The day is coming when we will interrogate the thyroid equation (hypo or hyper) in all our patients with the same fidelity that we inquire to-day into their previous history as regards tuberculosis, syphilis, and alcoholism."[2]

In conclusion, the main purport of this paper is to lay stress upon hypothyroidism as a causative factor in cases of irido-cyclitis and upon the usefulness, clinically, of its recognition. That the ciliary body, so sensitive to toxæmic influence, should readily respond to thyroid treatment is a natural sequence to the vascularity of its structure. Thus is placed in the hands of the ophthalmic surgeon a means of relief, yielding results which can be obtained in no other way. The dose of the extract employed by me for children beyond 5 years of age and for adults is 3 grains twice daily, and from this dosage I have never seen any ill-effects.

Wimpole-street, W.

FRACTURE OF THE PELVIS, WITH EXTRAPERITONEAL RUPTURE OF THE BLADDER.

By A. E. BLACKBURN, M.D. BRUX., M.R.C.S., &c.
AND
W. WARNER COOK, M.R.C.S., L.R.C.P. LOND.,

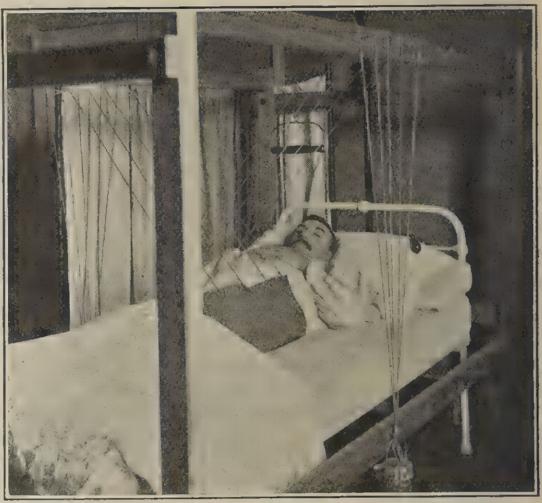
FRACTURE of the pelvis and rupture of the bladder are fairly common accidents, but the enormous separation of the pubes and the extensive damage to the bladder and prostate from such a simple cause seem to make this case unique.

The patient was a healthy farmer aged 45 years. The accident occurred on August 5th, 1914, whilst he was engaged in showing a horse for military purposes. He jumped on to the horse bareback. At the time he felt no pain, but after riding a few yards he felt a griping sensation "inside." This became so bad that he rolled off the horse; he was found in this condition and taken home. He was quite certain that he did not jump heavily on the horse, and he was equally certain that the horse did not buck, nor crush him in any way. He was not under the influence of alcohol. He had ridden horses for years, and times out of number he had mounted horses in a similar way. The accident occurred at 6 P.M.; he was seen by us at 7 P.M. He was in great pain and his scrotum and perineum were very swollen and discoloured, and his left leg was rotated outwards.

On first sight it appeared that the case might be a simple hæmatoma of the testis, considering the history of the accident, but as he had not passed urine for some time, and there was no bladder dulness, it was decided to pass a catheter. On passing a catheter a little bloody urine was withdrawn. It was considered advisable to remove the patient to a nursing home for operation, as his house was 10 miles from the town. He was operated upon at 1 A.M.

On making a suprapubic opening hæmorrhage was very free, and this was found to be coming from the region of the prostate, which was ripped up, along with the bladder. The rent in the bladder was so extensive that the hand could readily be passed into its cavity. The ramus of the left pubic bone was fractured near the symphysis, and the separation was over 6 inches in extent. As the hæmorrhage was so free and the patient was in such a critical condition any attempt at suture of the bladder was considered unadvisable, and he was merely packed with gauze and drainage-tubes inserted. His legs were tied together and the usual treatment for shock was carried out. He was not expected to recover. Hæmorrhage continued to be profuse for the next 24 hours, but the patient rallied and his condition next day was satisfactory.

FIG. 1.



The patient lying in the leather splint. The bed is surrounded by a wooden frame, cords are fastened to the leather and passed over the top rail of the frame; at the ends of the cord on either side is a tin containing shot. The tin on the left side contains 6 lb., the right 12 lb. The patient is "slung" in the same way as one slings a horse.

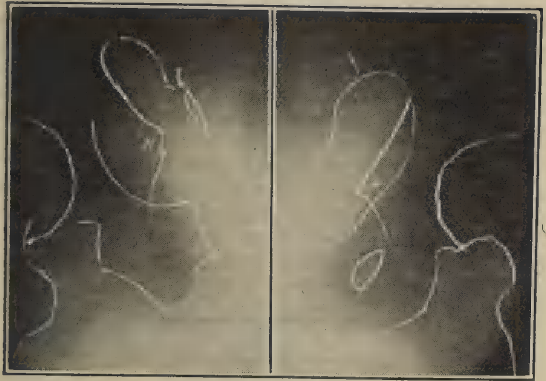
On August 9th the plugs were removed, and on the 11th, under an anæsthetic, a metal catheter was passed and tied in, the bladder washed out, and Irving's apparatus applied. The bladder was washed out twice daily, and urotropin and brandy were given regularly. About this time he appeared to be developing pneumonia. The temperature went up and nasal breathing was marked, but it subsided after more frequent bladder washings. On Sept. 3rd an attempt was made to draw the pubic bones close together, and a leather splint was applied with counter-extension and weights (Trendelenburg). (See Fig. 1.) The patient had complained of great pain and could not sleep, but from the day on which this splint was used he became more comfortable. On Oct. 14th he passed urine naturally, and the suprapubic opening closed about the end of November, and he was able to stand, but this gave him pain, and he was glad to return to his splint.

---

[2] American Medicine, April, 1914, p. 198.

On cystoscopic examination of the bladder in December, it was found to be perfectly healed, and no scarring was found. An X ray examination disclosed the fact that the bones were still about 1½ inches apart, and that the sacro-iliac joint has suffered partial dislocation; but in spite of this fact the patient is able to walk. The skiagram (Fig. 2) shows the present condition.

FIG. 2.



Skiagram of pelvis looking from behind. Left side: × shows partial dislocation of the left sacro-iliac articulation. The ilium is displaced upwards. Right side: × shows the normal position of the right sacro-iliac joint. The left os pubis is seen separated from the right; the fracture going through the symphysis, above which the coccyx appears. The bone is displaced upwards. The straight line shows the width of the separation of the pubic bones.

The case is interesting in the extensive injury produced by merely jumping on a horse, and the suggestion of congenital weakness of the pubic symphysis does not explain it. The use of the Trendelenburg splint for drawing the bones together we have not been able to find in any text-book, and are indebted to Mr. Thomson Walker for pointing it out in a French genito-urinary paper. In spite of the fact that no sutures were inserted into the bladder, it healed up perfectly, and the capacity does not appear materially altered. The patient is now pursuing his ordinary work as a farmer, walking easily for three miles at a stretch.

HYPERTRICHOSIS IN THE INSANE.

By C. T. EWART, M.D. ABERD.,
SENIOR ASSISTANT MEDICAL OFFICER, LONDON COUNTY ASYLUM, CLAYBURY.

ANYONE with an observant eye who happens to pass through the wards of an asylum cannot help but being struck with the number of female patients showing an excessive overgrowth of hair on the face—a number much larger than can be seen in any haphazard collection of women selected from the everyday world. The overgrowth is not a mere pencilling of down on the upper lip and chin, but hirsute appendages capable of arousing in some men a feeling of envy. It would also be observed that these cases are represented by a lusty and strong type of physique, thus conveying the impression that the overgrowth is correlated with animal vigour.

At the present time there are resident at Claybury Asylum ten cases of hypertrichosis. Two of these are married—one with two children and the other childless; the remainder are single and have no offspring. Two of the single women have an abundance of hair on their lower extremities, but in the remainder the distribution of hair is normal. All have menstruated regularly, height and weight are above the average, and the type of insanity in each is that of depression. The excessive amount of hair on the face has been developed in adolescent life and not after the climacteric. All being sensitive on the subject, to please them a razor has frequently to be used. Some even endeavour to get rid of the disfigurement by rubbing with pumice-stone. No history as to hereditary transmission can be elicited.

The question as to what are the causes leading to this form of hirsutism is shrouded in mystery, but I would venture to suggest that there is evidence which goes to show that the secretions of the suprarenal glands may be important factors. Before touching on this point it would be as well to remember the advice of Dr. T. B. Hyslop: "That not only may there exist a functional increase or a diminution of one type, but also a relative or compensatory increase or diminution of the secretion of one or several of the undamaged remainder. ...... It is warrantable to assume that a lesion of any important gland makes itself felt throughout the whole of the chemical interchanges of the body." I pass on to touch briefly on some of the secretions.

Ovaries and testicles.—With the development of the sexual organs there is marked growth of hair. In women the cessation of the sexual functions at the climacteric does in some cases correspond to the excessive growth of hair on the face; but, considering that all women pass through this change and so few who suffer from hypertrichosis, the cause of the overgrowth cannot altogether depend on the secretions or lack of secretions of these glands.

Thymus gland.—This gland apparently becomes functionless about puberty, and there is at this time an increase in growth of hair. It has been suggested that it is the thymic secretion which inhibits the sexual development with its associated hair growth. Removal strikingly impairs the development of the osseous system and the genitalia.

Thyroid gland.—When there is a diminution of secretion the hair of the scalp becomes scanty and prematurely grey, with a falling off from the eyebrows, eyelashes, axillæ, and pubis. With thyroid medication the hair again grows.

Pituitary gland.—This does not appear to have any influence on the growth of hair.

Suprarenal glands.—The cortex forms, in man, at least 90 per cent. of the entire bulk of the gland, and it is the enlargement of the cortex which characterises the adrenal glands of the higher animals. They exert a powerful influence on the growth of the hair, for in a few instances hypertrophy has been associated with early sexual development of hair. On the other hand, disappearance of the pubic hair and non-development of the genital organs have occurred in connexion with defective suprarenals. Dr. T. R. Elliott, of University College Hospital, states: "The cells of the cortex are derived from a mass of tissue close to the kidneys in the neighbourhood where the sex gland arises. As the latter, testis or ovary, descends to the pelvis, it carries with it buds from this mass which may be scattered along the line of descent and form accessory cortical adrenals along the spermatic veins. There is reason to believe that other buds are embedded in the sex gland itself, giving rise to the lutein cells of the ovary or the interstitial cells of the testis. By these cells are determined the sexual characteristics of the individual."

Some forms of cortical overgrowth cause an early adolescence and sexual precocity. The young male acquires hair on the face and pubes years before the proper time, and his body at nine years becomes that of a diminutive but strongly built man. The female, curiously enough, under like conditions, loses the characteristics of her sex, hair growing on the face and her body assuming a masculine contour. Dr. Gordon Holmes describes a case in which a perfectly normal young woman had at the age of 20 ceased to menstruate, and this she attributed to fright. A beard commenced to grow and the body assumed a masculine appearance. Four years later a tumour of the right adrenal was removed, but time has not yet permitted of the hoped-for result—the return to femaleness.

The medullary portion of the suprarenals has, apparently, only a very close connexion with the nerves of the sympathetic system.

From the presence of the lanugo, or down, on the human fœtus we may infer that man is descended from some animal which was born hairy and remained so during life. In the infancy of the race, and before man started to conquer the earth from the Equator to the Arctic regions, a complete covering of hair may have been a useful protection, not only from wet weather but from sudden chills. Gradually, as his brain developed and his intelligence evolved, by natural and sexual selection he cast off his hairy clothing and supplied himself with substitutes derived from the animal and vegetable worlds. Other animals find a niche in the world into which they fit themselves, rest, and are thankful, but insurgent man travels along the open road and no niche is good enough for him. This being so, he has to be capable of adapting himself to all conditions of existence, as otherwise he would have found himself in a cul-de-sac. The power ever thrusting him forward is the function we term mind, which precedes and creates for itself the structure we call body and is itself an evolutionary product. The loss of hair is thus correlated with the growth of intellect, and this may to some extent explain the baldness which is always conspicuous by its presence at the meetings of learned societies. The superman will most likely be a completely hairless creature. Darwin holds that, as the body in woman is less hairy than in man and as this character is common to all races, it is right to conclude that it was our female semi-human ancestors who were first divested of hair for some natural advantage, and that this partial loss, because it exposed the beauty of the skin, became highly esteemed as an ornament by our male progenitors, and so gradually by sexual selection the denudation proceeded. With civilised man the sense of beauty may be intimately associated with complex ideas and trains of thought, but in the great majority of animals the taste for the beautiful is confined, so far as we can judge, to the mere attraction of the opposite sex. Where females have been the selectors the males are more highly ornamental; where males exercise the right of choice the opposite occurs. In the case of woman man has decided that smooth cheeks are ornamental, and this becomes transmitted exclusively to the female offspring, and those with an overgrowth are not sought for as mates and therefore die out. Anyone who has seen pictures of the Siamese hairy family must admit that they create feelings of repulsion. The beard is peculiar to man, and because it gives an aspect of virility to the face it acts as an attraction to the woman, thus becoming a secondary sexual character, and I have yet to hear of a civilised nation which looks upon a beard in a woman as anything else but a monstrosity. It revives the old prejudice that anyone with this stigma represented a person on whom Nature had branded a mark of mental and moral degeneracy.

> But thou art neither like thy sire or dam,
> But like a foul unshapen stigmatic—
> Marked by the Destinies to be avoided
> As venom toads or lizard's dreadful stings.
>
> —*Henry VI.*

The evolution and maintenance of sex is definitely for the purpose of reproduction, and is ordained for the sake of the race and the future. It is an instrument of progress becoming more powerful, more delicate, and more subtle in its work as the ages roll by. This is the evidence afforded by a survey of living forms in general, and emphasises the arguments of those who say that the trend of evolution is towards an increase of sex differences, and that, if history is to be trusted, there would appear to be a natural and indispensable decree for an increase of feminism in woman and masculinity in man. But if so, what is the inner meaning of the modern mode of clean-shaven faces? Is a moustache to be doomed because it is not only a constant emblem to a woman that a man is a man, but also reminds her of the unkind fate which condemns her to be born a female? Has facial hair lost its sexual significance because of the creation by the pampered luxury of peace of a feeling in woman that she no longer needs a protector, and will the war restore a beard to its original importance?

Claybury.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTE ON A LITTLE-RECOGNISED FORM OF CARDIAC THROMBOSIS.

By SAMUEL WEST, M.D. OXON., F.R.C.P. LOND.,
CONSULTING PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

THE common forms of cardiac thrombosis are: (1) the soft bulky gelatinous clots, described as *post-mortem clots;* and (2) the tough, more or less, decolorised clots which form the chief part of the *vegetations* on diseased portions of the endocardium, especially in connexion with the valves. As rarer forms are (3) larger and more or less *rounded masses* found in dilated cavities; they are usually attached to the cardiac walls, but may be free, when they have been called (4) *ball thrombi.* It is the pathological rarity of these two last forms that gives them their chief interest.

The form of cardiac thrombosis with which I wish to deal is of an entirely different character; it occurs in patients who have been long a-dying, as in phthisis or malignant disease. The clots present the usual characters of ante-mortem clots, being firm and tough, pale, and fibrinous. They are thin and flat and moulded to the shape of the ventricles and auricles, and represent these cavities in the stage of extreme contraction. The thickness varies in different parts, but averages one-eighth to one-quarter of an inch. The clot starts in the ventricles, behind the trabeculæ carneæ, and in the auricles among the rugosities of the appendix, and this connexion keeps them fixed. In the ventricle the clots form a thin, flat, triangular, pancake-like mass, 3 inches, it may be, in length and 1 to 2 inches in greatest breadth. A thin band may pass through the auriculo-ventricular orifice, to be continuous with a similar flat clot on the auricle, from which string-like processes may extend for some distance into the branches of the pulmonary artery and veins. Clots of this kind are, as would be expected, commonest on the right side of the heart, but they may occur on the left or on both sides together. Apart from their pathological interest these clots are of clinical importance, because they may become detached and thus cause fatal embolism. This cause of pulmonary embolism should be borne in mind when no source for the clot can be discovered in the veins.

Embolism of the aorta might similarly occur, and a case of this kind I recorded some years ago. The patient died suddenly. The main trunk of the aorta was found plugged with a mass of tough decolorised clot of considerable size. On unravelling this in water it opened out into a thin flat clot such as I have described, which could be readily placed *in situ*, and corresponded exactly with the cavities of the left ventricle and auricle.

It is strange that this form of cardiac thrombosis has not received more attention, as it is by no means rare.

Wimpole-street, W.

URETHRAL CALCULUS IMPACTED FOR 15 YEARS.

BY T. BATES, JUN., M.B., B.S. LOND., F.R.C.S. ENG.

THE patient was a male, aged 39 years, unmarried. The following history was given. The patient was circumcised in 1899 at the Middlesex Hospital. In 1900 he was seized with acute pain in the penis. A small calculus became lodged in the fossa navicularis. He consulted a medical man, who prescribed some medicine for him, and shortly afterwards he left London, since which date he had consulted no medical man, although the calculus remained *in situ*. I saw him on account of severe pain and swelling in the penis. I then found the distal half of the penis much swollen. Thin watery pus was discharging from the urethra. There was a muco-cutaneous fistula opening behind the glans penis.

The calculus, exact size. The upper view shows the dorsal aspect and the lower view shows the right lateral aspect of the calculus.

Operation.—An incision was made from the meatus urinarius to the muco-cutaneous fistula, the stone removed, and hæmorrhage controlled by catgut suture of the wound. A No. 12 bougie was passed once a week for four months as a precaution against stricture.

The stone weighs 58 grains; size $1\frac{3}{8} \times \frac{1}{2}$ in. The anterior third is smooth and blunt; the posterior two-thirds are rough and pointed. The anterior half is hollow, the walls being laminated, the inner laminæ being dark in colour and the outer ones pale.

THE Royal Dental Hospital, Leicester-square, has received a donation of £500 from the trustees of Smith's (Kensington Estate) Charity.

Medical Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Dermatitis Herpetiformis.—Urinary Concretions.—Cases of Landry's Paralysis, Myasthenia Gravis, and Epileptic Automatism.

A MEETING of this section was held on April 23rd, Professor J. A. LINDSAY, the President, being in the chair.

Dr. C. M. O'BRIEN showed a boy, aged 14, who had been suffering from Dermatitis Herpetiformis since he was 3 months old. He was one of a family of nine healthy children, and up to the time of vaccination was in good health. He then developed a rash, which in its early stages caused much itching, was multiform, and well marked on the arms and legs. A peculiarity was its persistence and recurrence. It never totally disappeared.—Dr. WALTER G. SMITH said the disease was rare; he suggested "dermatitis multiformis" as a better name. He considered the persistence and recurrence its distinguishing marks. He looked upon treatment as of no avail.

Dr. WALTER SMITH read a paper on Urinary Concretions, their Origin and Modes of Formation, in which the following questions were brought forward: 1. Is there any essential difference between gravel (sand) and calculus? 2. Is there any general theory of calculus formation? 3. Is there a scale of relative frequency of the different species of calculi? 4. What do we know as to the determining factors leading towards or producing calculi? 5. How far can we trace the coöperation or interaction of colloids and crystalloids in their production? 6. Has the frequency of calculi sensibly decreased within recent times. Stress was laid upon conditions of altered or perverted metabolism in the etiology of calculus, and attention was called to our ignorance of the pathology of gout and to the exaggerated statements as to the alleged pernicious effects of uric acid in the blood. The conditions relating to relative solubility were discussed in some detail, and it was insisted that the relations between colloids and crystalloids are of prime importance in the etiology of urinary concretions.—Sir JOHN MOORE recalled his experience of 40 years ago at the Meath Hospital, when the surgeons were almost constantly operating for stone. He thought the prevalence of stone had decreased in recent years. He had always connected the subsidence of ordinary calculus with the introduction of Vartry water.—Professor H. METTAM said that urinary calculi, chiefly oxalate, carbonate, or mixtures, were met with in the domesticated animals. In a specimen shown at the Section of Pathology renal calculi were found in the lymphatic spaces outside the tubules. In the lower animals calculi of enormous size were met with. It had been observed that rams fed on mangolds, which are very rich in sugar, frequently developed calculi.—Dr. A. R. PARSONS asked for an explanation of the frequent occurrence of calcium oxalate crystals in the urine of diabetics.—Professor E. J. MCWEENEY said that during the past 20 years he had examined from 50 to 60 ordinary calculi and was strongly struck by the extremely dark colour of these oxalate of lime calculi; an oxalate of lime calculus found in the pelvis of the kidney was absolutely jet black with a very polished surface. This dark pigmentation of calcium oxalate calculi might be correlated with the fact that their surfaces are so rough that they produce small hæmorrhages.—The PRESIDENT said that in his experience in the North of Ireland calculus was rare, and he thought that a decrease had come about in recent times. The decrease might be accounted for by the extreme rarity of gout, which was much more common some years ago.—Dr. SMITH replied.

The PRESIDENT read the notes of the following three cases. 1. A case of Landry's Disease. He discussed the possibility of the case being one of acute ascending myelitis, acute poliomyelitis, or acute toxic polyneuritis, but was of opinion that these conditions could be excluded, and that the case was a genuine example of Landry's syndrome. 2. A case of Myasthenia Gravis. The points of distinction between myasthenia gravis and cases of aggravated neurasthenia were discussed, and stress was laid upon the predominance of muscle fatigue, the myasthenic reaction, the condition of the reflexes, the absence of pain, the absence of morbid introspection, and the alternating character of the symptoms as characteristic of the former disease. 3. A case of Automatism. The patient was a man, aged 60, of temperate habits and a history of good health. There was no history of hereditary nervous disease, alcoholism, or syphilis. His general health was excellent, and his weight was 14 st. 7 lb. There was no evidence of organic disease in any of the viscera. His story was that on several occasions he had found himself at considerable distances from his office without any recollection of what had happened in the interval. He had never had a convulsion, had never fallen or hurt himself, had never passed urine during an attack, and his condition had never excited the notice of any of those persons with whom he was associated. On recovering from a seizure he felt perfectly well, and there were no after phenomena. Physical examination was entirely negative. The patient was put upon a course of bromide and belladonna, and in a short time the attacks ceased. When last seen he had been free from attacks for a period of nearly five years.—Dr. H. C. DRURY considered that the first two cases were without question, but the third reminded him of a case of his own which he looked upon as of the nature of *petit mal.*—Dr. PARSONS agreed that the third case was one of *petit mal.* He recalled the case of a patient of his which ended fatally. At the necropsy nothing could be discovered wrong with the brain.—Dr. W. R. DAWSON agreed that the second case was not neurasthenia. In the third case, while listening to Professor Lindsay's account, he had made a diagnosis of *petit mal.* He considered the fact that the fits had ceased was an example of the good results produced by the combination of belladonna and bromide.—Dr. H. T. BEWLEY also discussed the first case.

The PRESIDENT, replying, agreed with the name of *petit mal* as better fitting the third case.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

"*Anger.*"—*Research in Connexion with Causation of Insanity.*

THE quarterly meeting of this association was held in the rooms of the Medical Society of London on May 18th, Dr. DAVID G. THOMSON, the President, being in the chair. Dr. Thomson having referred to the services to psychological medicine of the late Sir Thomas Clouston, the meeting passed a resolution of sympathy with Sir Thomas Clouston's relatives, the members rising in their places.

The PRESIDENT also said that Dr. J. Beveridge Spence and Dr. T. Seymour Tuke had recently lost their sons in battle, and the meeting expressed its sympathy with the bereaved parents.

About 100 books were presented to the library by Dr. T. B. Hyslop, who was cordially thanked for his generous gift.

Dr. HYSLOP then read a paper on "Anger," and said that many authorities considered that Germany was now running amok in an epidemic of maniacal fury. He regarded this as an instance of epidemic psychopathy, a repetition of which humanity was not likely to permit.—The subject was discussed by Sir GEORGE SAVAGE, Mr. H. F. HAYES NEWINGTON, Dr. J. N. SERGEANT, and Mr. W. F. SAMUELS.

Dr. DAVID ORR read a paper on Research in Connexion with the Causation of Insanity. Such research in this country, he said, up to the present time had been either isolated, neglected, or starved. At one period of our knowledge isolated effort could make some headway, but now the problems were much more complex, rendering essential the coöperation of several species of workers. Research had come to mean specialisation in a branch after a thoroughly broad preliminary training, and this must be given in a properly equipped central laboratory. Such laboratory must be prepared to give instruction in anatomy, physiology, pathology, bacteriology, chemistry, and serology as applied to the nervous system. There were many examples in history of the futility of attacking problems from a narrow standpoint. Dejerine had declared that in the study of the lesions in aphasia, macroscopic observation was not sufficient; there must be microscopical examination in serial stained sections of the affected hemisphere, or even of both hemispheres. Only by this means could the limits of the lesion be determined and the questions still under debate be solved. This must apply even more truly to such conditions as various types of insanity, epilepsy, agnosia, apraxia, &c. And there must be complete reciprocity between the laboratory and the asylum. Investigators in the domain of neuro-pathology must no longer recognise any line of demarcation between the brain and the nervous system. Clinical insanity, he considered, was best taught in a clinic where the cases were seen in the stage of early development; and the clinic should be in close touch with the laboratory. Both should be conveniently near to a medical school whose teachers could give special lectures and expert advice. No training could be complete without adequate clinical instruction. Each asylum should have its own pathological department, in which those who had been trained in broad neurology could work out problems for themselves; when in difficulties the central institute could be drawn upon for expert advice. The county asylum was not the best place in which to learn, because so seldom were cases seen there in the early stage.—Mr. HAYES NEWINGTON hoped that those who would find the money for research would be impressed by what Dr. Orr had advanced; he had made out an excellent case for it.—Dr. HUBERT J. NORMAN expressed the view of many in the asylum service as to the small opportunity they received for doing any research, though they fully saw the necessity of it. To conduct this work men must have the enthusiasm for it which the author had shown.—Dr. HARVEY BAIRD spoke of the good work being done at Cardiff Mental Hospital, due largely to the keenness of the superintendent, who succeeded in impressing the borough authorities as to the need for supporting the work.

Dr. ORR replied, expressing the view that the necessary money would be forthcoming.

ROENTGEN SOCIETY.—The annual general meeting of this society will be held on Tuesday next, June 1st, at 8.15 P.M., at the Cancer Hospital, Fulham-road, S.W. The annual report and the honorary treasurer's report will be received, and a ballot will take place to chose the president, members of council, and officers for the ensuing session. The electrical and radio-therapeutic department of the hospital will be open for inspection and there will be a number of demonstrations given. Members desirous of showing new apparatus, negatives, or lantern slides are requested to communicate with the honorary secretary, Dr. Robert Knox, 7, Harley-street, London, W.

THE HENRY SAXON SNELL PRIZE.—This prize, which was founded to encourage improvements in the construction or adaptation of sanitary appliances, is awarded by the council of the Royal Sanitary Institute every third year. The prize consists of 50 guineas and a silver medal, and it will be awarded this year for an essay on Suggestions for Improvements in the Sanitary Arrangements and Appliances on Board Ship for Passengers and for Cattle. Further particulars may be obtained from the secretary of the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W.

KING'S COLLEGE: UNIVERSITY OF LONDON.—We are informed that the course of lectures by Professor Brodie on the Gases of the Blood, announced last week, will not be delivered owing to Professor Brodie's services being required for military purposes.

ASYLUM WORKERS' ASSOCIATION.—The annual meeting of this association was held on May 19th, when Sir John Jardine, K.C.I.E., M.P., presided. It was stated in the report that although the value of the association had never been more apparent, the membership had shown a decline for the year 1914.

PLAGUE IN HONG-KONG.—The Colonial Office reports 13 cases of plague, with 12 deaths, at Hong-Kong in the week ending May 22nd.

Reviews and Notices of Books.

Abdominal Operations.

By Sir BERKELEY MOYNIHAN, M.S. Lond., F.R.C.S. Eng. Third edition, revised. In two volumes, fully illustrated. Pp. 488 and 492. London and Philadelphia: W. B. Saunders Company. 1914. Price 42*s.* net.

THE field of surgery is so vast that it is now, more than at any previous time, necessary to limit the purview of any work on surgery if the study of it is to be at all thorough; and at the present time, when specialism for good or evil has assumed such an important place in modern medicine, it is more than ever essential to confine the subject within reasonable boundaries.

When the first edition of Sir Berkeley Moynihan's work on the surgery of the abdomen appeared it was generally recognised that an extremely valuable treatise had been presented to the English-speaking peoples, and one which from the originality and experience of the author should prove of the greatest value to surgeons. This, the third, edition has grown to two volumes, and when we consider the importance of the subject and the advances which are being made almost daily in this branch of surgery, we must acknowledge that there is ample reason for the enlargement of the work. Although the book is entitled "Abdominal Surgery" there are certain intentional omissions; only those abdominal operations are included which are common to the two sexes, for no gynæcological operations have been introduced. Moreover, the surgery of organs like the kidney and the bladder, which are partly intra- and partly extra-peritoneal, is omitted, and the various operations for hernia are not included. In a work such as this the author was naturally sometimes in doubt as to whether he should include a certain operation or not; and we think that Sir Berkeley Moynihan has acted wisely in including in the work only those operations which he practises himself, and a few others which are generally recognised as worthy of recognition. One remarkable fact deserves mention, and that is that no allusion is made to mechanical aids for the union of bowel or stomach; the author holds that the purpose of these aids has been served and that their interest is now only historical; as good or even better results can be obtained without them.

It is needless to discuss the whole work in detail, but we may say that in this, as in the other writings of the author, the facts are given in simple language, and he speaks with the assurance of one who knows his subject. The illustrations are numerous and clear, and the printing is all that can be desired.

The Infant: Nutrition and Management.

By ERIC PRITCHARD, M.A., M.D. Oxon., M.R.C.P. Lond.; Physician to Queen's Hospital for Children; Physician to Out-patients, City of London Hospital for Diseases of the Chest, Victoria Park, &c. London: Edward Arnold. 1914. Pp. 265. Price 3*s.* 6*d.* net.

THE subject of the nutrition and management of the infant is one which, in view of its great national importance, has within recent years received very marked attention, and large numbers of text-books and popular manuals have appeared. The vexed question of infant mortality and the methods of reducing it cannot receive too much attention, more especially from those who, like Dr. Pritchard, have devoted special practical attention to the subject. We therefore welcome the little book before us as a thoughtful, suggestive, and stimulating contribution to this matter. Although many of the views expressed in it are new and some of them heterodox, they are obviously the result of careful thought, wide experience, and a practical examination of the problems involved.

The subject of breast feeding is first dealt with, and great stress is laid upon the importance of perseverance in the attempts to secure breast feeding in spite of difficulties. Numerous practical hints are given of measures to promote a regular and satisfactory flow of milk. Some interesting observations are next given on the nutrition of the infant and on the determination of the quantitative food requirements. By means of the "test-feed" in breast-fed cases Dr. Pritchard has accumulated some striking data. He rightly points out that it is unscientific to prepare hard-and-fast tables for general application. Each case must be considered individually, since its needs depend upon the rate of growth, the work done in bodily movements, and the rate of heat loss of the particular infant. He arrives at the conclusion that the demand for food in an infant can be increased by less clothing, more air, and more exercise. The motor functions of the digestive tract and the training of nerve centres next receive attention, and some valuable suggestions are made as to the proper education of these functions and the avoidance of disturbing factors. The subject of constipation is examined in some detail, and here the importance of quantitative and qualitative defects in diet is emphasised, as well as the value of endeavours to induce regularity of habit. Dr. Pritchard inveighs strongly against the administration of purgatives and enemata, especially against the dose of castor oil so frequently given to infants in the first few hours of life, which he regards as often provocative of subsequent constipation. Some common symptoms in infancy, such as marasmus, vomiting, crying, coughs, diarrhœa, thrush, and sore buttocks, are next examined, and the rational treatment of each is considered. A chapter is devoted to a consideration of the uses of dried milk in infant feeding, of which Dr. Pritchard apparently has a high opinion. The uses of petroleum are next dealt with in detail, and some useful directions are given in regard to preparation and dosage. Other subjects considered are the causation of convulsions in infancy and the causation and treatment of rickets. The concluding chapter is devoted to a matter to which Dr. Pritchard has devoted special attention—viz., the instruction of mothers in mother-craft.

We can strongly recommend this book to the general practitioner, and especially to those concerned in the management of infant consultations or of mother-craft centres.

Text-book of Public Health.

By E. W. HOPE, M.D. Edin., D.Sc., Professor of Public Health, University of Liverpool. Eighth edition, revised and enlarged. Edinburgh: E. and S. Livingstone. Pp. 267. Price 5*s.* net.

PUBLIC health and forensic medicine used frequently to be taught at the medical schools by the same lecturer and in the same course, and a standard text-book in both branches, which served for generations of students, was the volume known as "Husband." The two subjects are now seldom thus combined in teaching, and Dr. Hope has been well advised to issue separately the portion of

"Husband's Forensic Medicine" for which he was responsible. This little volume should go a long way to meet the requirements of the medical student or the practitioner reading for the Diploma in Public Health, for whom it is intended. It is full of well-arranged information, given with the lucidity which characterises Dr. Hope's writings, and is well illustrated. The main object of the book has been kept in view throughout, and care has been taken to quote sound authorities and to draw upon the official documents and reports which govern the every-day practice of medical officers of health and school medical officers. Some of the most useful information in the volume is derived from Dr. Hope's special experience in Liverpool, and as a whole the work deals essentially with the practice of public health in large urban communities.

The new edition is well up to date in such matters as the methods for dealing with tuberculosis which have followed the National Insurance Acts, and other recent legislation and changes of administration which bear on the curriculum of instruction in public hygiene at the present day.

Zoology: An Elementary Text-book.

By A. E. Shipley, D.Sc., F.R.S., Master of Christ's College, Cambridge, and E. W. MacBride, D.Sc., F.R.S., Professor of Zoology at the Imperial College. Cambridge University Press. Third edition. Pp. 752. Price 12*s.* 6*d.* net.

In view of the authoritative names of the two authors and of the fact that the present is the third edition of their useful text-book, it will hardly be expected that much criticism can be applied to this manual of zoology—that is, in the way of detection of error—though, as they tell us in the preface, the third edition is in some parts substantially altered. There are, however, a few points to which we should like to direct their attention, where some little improvement can be introduced in a succeeding edition.

For instance, in dealing with the structure of birds (p. 629) the authors write that "according to one of the best bird specialists the external characters furnish just as reliable data as the ill-known internal organs" for the classification of this group. It is not clear whether this is in effect a quotation or a mere verbal *ipse dixit* of the eminent one. In any case it is singularly at variance with fact; for it would be hard, if not impossible, to find any group of animals whose internal anatomy has been studied in greater detail or more comprehensively than has been the case with birds. There is not a bone, not a muscle, not a viscus that has not been treated of by one or more of the seven or eight zoologists who have specially dealt with these vertebrates.

In describing the skull of Chimæra the authors naturally use the term "autostylic," introduced by Professor Huxley in his well-known memoir upon the skull of Ceratodus, for the suspensory condition of the jaws. Having decided to adopt this widely used word it was unnecessary, as we think, to replace it on p. 473 by "holostylic." The disadvantage of the "type system" in treatises on zoology (which, however, it must be confessed, can hardly be avoided) is, to our mind, that it is apt to give wrong impressions while correctly stating absolute fact. Thus, the authors of the present treatise, in distinguishing between the earthworm and the leech, remark that "in leeches, unlike the condition in the earthworm, the genital pores are single and median." The student might go away with the fixed idea that this statement covers all leeches and all earthworms, which would, of course, be incorrect. As a matter of fact this danger could be easily avoided by adding after the word "earthworm" some such phrase as "but not in all genera." A slight blemish seems to us to be shown in the definition (p. 166) of the Hirudinea, where the dogmatic statement of characters is immediately followed by a definition of the suborder Acanthobdellidæ in which several of these characters are shown not to apply. This could have been avoided by the use of such a word as "generally," interspersed with the requisite liberality.

It must not be assumed from these few observations that we are not impressed by the general and dependable accuracy, and thus usefulness, of this very handy volume. We merely proffer some suggestions for the future.

Significato Bio-filosofico della Guerra.

By Dr. William Mackenzie. Genoa. 1915. Pp. 101. Price 2 lire.

This little brochure is a praiseworthy but somewhat hopeless attempt to solve by means of biological and metaphysical methods the question, "Why do the heathen rage so furiously?" The author starts with the premise that every cell has two apparent tendencies—to become more complex and more specialised—hence grades and types become evolved. The same process applies to groups, the final evolution of which is seen in national states. Further, as every organism must fight in order to exist, this applies also to states, but the author points out that the "struggle for life" does not constitute the exclusive protection of the biological edifice, it is only a mode, a partial aspect of development, the other aspect being strictly complementary and found in "collaboration," which may attain to complete denial of self for the reciprocal advantage of the organic constituents.

Nations and states, says Dr. Mackenzie, live as if they wished to become more and more "national" and at the same time more and more "dominant." The entire drama of history according to his theory consists in the undoings of one or the other tendency and in the temporary over-ridings of one over the other; the drama—that is to say, of oppressed nations, as also of crumbling empires, from whose ashes there arise again and for ever other nations and empires. The populace, or those who think they govern them, very often maintain, and in good faith, that the object of a given war resides in the affirmation or in the defence of a given right, interest, or principle; nevertheless, whatever their apparent interests or principles may be, the ultimate scope of every war, whether confessed by those responsible for it or not, must ever be the aggrandisement of the nation or state, either directly by some positive addition or indirectly by liberation from some burden or menace. The same duplex necessity of sustenance and increase which is incumbent on the smallest protozoon in its drop of water weighs equally on nations and states; peoples with their own struggles, gigantic in comparison with those of the protozoon, have no other object than to increase in space and time, although they themselves know nothing of it.

Whether Dr. Mackenzie has satisfactorily and convincingly proved his thesis must be left for the reader to judge for himself, but to help his decision we may summarise two judgments passed by the author on two contemporary students of war—

Wundt and Bergson. The former professes to find the determining factors of the present war in a "low desire for gain" and in the "diplomatic intrigues" of those who direct the conflict against his compatriots, but above all he believes that the origin of the war must be ascribed to the will of a king (now deceased) and an ambitious group of political adventurers. A strange error, comments Dr. Mackenzie, and full of suggestion is that of this learned man who during his long scientific career has been occupied with the study of psychology, and especially the psychology of peoples. How clearly the hidden will of the nation speaks through his mouth, which befogs his thought, otherwise so clear, and makes it a blind instrument of war!

But little better is the conclusion arrived at by Bergson in his well-known academical and bellicose treatise, which is justly celebrated for its elevated style. This treatise contains in substance the startling and more or less explicit assertion that the present war is above all a struggle of the material against the spiritual, and, as is natural, the illustrious philosopher finds all the spiritual on his own side and all the material on that of the enemy. With regard to this attitude Dr. Mackenzie says with truth that science and philosophy will gain more by the silence than by the publications and speeches of those scientists and philosophers who in times of difficulty for their own country, and for the whole world, make a profession of political faith, thinking to further it by biological arguments which do not fit in with any faith. Such lucubrations conduce to a single and most deplorable result—that of causing and fostering that ignorant hate among men which is the main "enemy" to be fought against.

Radiography, X Ray Therapeutics, and Radium Therapy.

By ROBERT KNOX, M.D. Edin., M.R.C.S., L.R.C.P. Lond., Honorary Radiographer, King's College Hospital; Director, Electrical and Radiotherapeutic Department, Cancer Hospital, London, &c. With 64 full-page plates and 245 illustrations in the text. London: A. and C. Black, Limited. 1915. Pp. 406. Price 25*s.* net.

THIS is the first really comprehensive volume on the whole subject of the X rays and radium that has been brought out by a British author. While we have had many similar volumes in the past they have emanated for the most part from the continent and America. This is not because British radiologists have been behind in their researches, but rather because as a class they are more content to wait until they are sure of their ground before stating their views in permanent form. As a matter of fact, a very large proportion of the writings of foreign radiologists have added little to our permanent knowledge of radiology.

In the present volume we have a very complete treatise on the present state of our knowledge; so complete and comprehensive is it that in our opinion it goes rather beyond the author's aim, "to present to the student and practitioner in as concise and as practical a form as possible the essential points in radiography and radium therapy." The beginner who attempts to get his knowledge of a subject so highly technical from this volume will find himself rather bewildered with the task before him. The book appeals more to those who have acquired their first principles and desire to increase their knowledge extensively. This applies particularly to the first chapters dealing with apparatus. A perusal of this part would leave the beginner with a sense of incompleteness; however ample it may be for those whose technical knowledge is fairly extensive, we do not think it meets the requirements of that greater number of aspiring radiologists whose attainments in this direction are of a very sketchy character. As regards the illustrations in this section, it is perhaps unfortunate at the present time that so many of them are from the catalogues of Teutonic manufacturers. Diagrams are more valuable to the student than illustrations of the finished article of one or other maker, but they require to be carefully prepared and selected. In this connexion we may instance the diagram of a centrifugal mercury interrupter on p. 17. We think the average beginner will find no little difficulty, with only this diagram before him, in understanding how this apparatus works. The same criticism applies to the section on X ray tubes and the various accessory appliances used in radiology. Fundamental principles are passed over too briefly, there are too many catalogue illustrations, and too few explanatory diagrams for a work that sets out to teach the beginner.

When we come to the practical application of the X rays in the diagnosis and treatment of injuries and diseases, we have nothing but praise for the scope of the work Methods are clearly described and the resulting plates are illustrated profusely and well. A valuable feature of the illustrations is that all are shown in duplicate, one as a negative and the other as a positive. As a radiologist almost invariably bases his opinions on the negative plates their reproduction in this form is a very decided help to the student in familiarising himself with the immediate results of his work. A very useful chapter is that on the development of the bones, showing the appearances of the epiphyses at various ages. This will be of great help in the interpretation of plates made from young subjects—a most difficult matter at times. The chapters on the examination of the thoracic, abdominal, and pelvic organs are complete and instructive. There are few who will not find here many valuable suggestions, and as this is a branch of radio-diagnosis that is bound to be increasingly important as time goes on, a study of the whole section of the work is recommended.

In the section on X ray therapeutics we find the same thoroughness displayed as in the previous part. The various forms of technique, methods of dosage, and other necessary details are supplied in a clear and concise manner. Suitable modifications are given for the treatment of different diseases, and numerous illustrations show the effects produced after treatment by the X rays, some of the cases of inoperable malignant disease being improved in a remarkable manner.

The last part of the book deals with the physics and application of the rays from radium in the treatment of disease, the section on physics having been contributed by Mr. C. E. S. Phillips. This part of the work will be found a valuable guide.

The book, which has been printed and published in an excellent manner, is bound to achieve success.

A System of Veterinary Medicine.

By Various Writers. Edited by E. WALLIS HOARE, F.R.C.V.S. Vol. II.: General Diseases; Parasites. London: Baillière, Tindall, and Cox. 1915. Pp. xx. + 1600. Price of the two volumes 50*s.* complete.

IT is many years since an authoritative work on veterinary medicine was produced in the British Isles, and since that time great advance has been made in the science. Many a practitioner in veterinary medicine has felt for some time that his own knowledge, limited as it necessarily must be by his opportunities, was still ahead of that supplied by the text-books, and that he could gain little progressive information from a perusal of their pages. It was somewhat of a reproach that no really good and recent standard British work of reference existed to guide, influence, and advance the knowledge of the veterinary surgeon. The reproach began to disappear when Mr. Hoare's System was issued. The information thus supplied to the veterinary profession has been derived from numerous sources, is presented in plain language, has been furnished by many of the best minds in the veterinary profession, and supervised by an editor who stands high as a clinician and scientific observer.

The first volume of the "System of Veterinary Medicine," it may be remembered, dealt with the "Microbial Diseases" of the various animals. The second deals with "General Diseases." Here the diseases described are, with few exceptions, those frequently found in this country—those, indeed, occurring almost daily among animal patients. All the contributors, 15 in number, are specialists in their several domains and have had extensive experience in treating the diseases of the horse, cow, sheep, pig, dog, cat, bird, and goat, upon which they write.

The editor writes on the diseases of the digestive system in the horse. His communications to the veterinary periodicals are evidence that he has spent years of study and research in trying to simplify some of the difficulties of diagnosis which here present themselves, and to suggest lines of rational treatment. He has, we think, succeeded in producing an admirable exposition of the subject. The ailments of the alimentary system in the other animals are also comprehensively and adequately dealt with, a special word of praise being due to the authors of the articles in this section on the ox (Mr. H. Begg, F.R.C.V.S.), the dog (Mr. E. Wallis Hoare, F.R.C.V.S.), and the pig (Mr. G. Mayall, M.R.C.V.S.). The division of the digestive ailments in the ox is good, and the treatments advised are uncomplicated and likely to be profitable and effective. The consideration of diseases of the digestive system in the pig fill a gap too frequently noticeable in books on this animal. A good knowledge of feeding, hygiene, and the physiology of digestion in porcines will be profitable alike to the professional adviser, the breeder, and the owner. The various forms of respiratory, urinary, circulatory, nervous, and parasitic disease receive full notice, and the work concludes with a section on poisons, and an appendix on the disease of sheep called "scrapie."

We have here a store of information, indispensable alike to veterinarians and students of comparative pathology. The contributions are from trustworthy sources and the book is well arranged. The publishers also have done their work well.

JOURNALS AND MAGAZINES.

The Journal of Comparative Pathology and Therapeutics. Vol. XXVIII., Part I. March, 1915.—In the March number, which is the last number of this valuable journal to reach our hands, there is abundant evidence that good work is being done by the veterinary profession. Captain E. Clive Webb, A.V.C., F.R.C.V.S., gives some results of Transmission Experiments and Arsenical Treatment of Trypanosomiasis of Donkeys and Mules in the Anglo-Egyptian Sudan, from which he concludes that arsenic appears to have a specific trypanocidal action in a large percentage of cases and clears the blood of trypanosomes. He believes that he may claim about 45 per cent. of cures, but justly observes that this claim cannot be made good until the cases have been under observation for a longer period. He maintains that to obtain successful results one must be prepared for casualties due to susceptibility and overdosage.—H. R. Seddon, B.V.Sc., of the Veterinary Research Institute, University of Melbourne, describes some observations on the methods of using the agglutination test in the diagnosis of the disease in bovines caused by the bacillus of contagious abortion. He uses vaginal or uterine exudates or the fluids from the fœtus or fœtal membranes, blood serum, or milk. He gives an account of the technique employed, describes the quantitative factors in the agglutination reaction, and comes to the conclusion that the method is of distinct value in making a diagnosis.—Principal Mettam, M.R.C.V.S., B.Sc., Royal Veterinary College of Ireland, Dublin, describes a case of lympho-sarcoma in the horse with arterio-sclerotic changes in the heart and lungs, a case of arterial sclerosis in a dog, two different malignant growths in the same dog, and an embryoma of the brain of the horse.—H. L. Watson-Wemyss, F.R.C.P. Edin., gives a sound summary of recent work on vitamines, especially in relation to beri-beri, the scurvy groups of diseases, pellagra, rickets, and tetany, and also on vitamines in their relation to growth, and calls special attention to von Noorden's oatmeal treatment of diabetes.—C. M. Wenyon, M.B., B.S., B.Sc. Lond, Director of Research in the Tropics to the Wellcome Bureau of Scientific Research, writes on the organisms found in piroplasmosis of Rhodesian sheep as observed by Bevan.—J. A. Griffiths, M.R.C.V.S., Department of Agriculture, Veterinary Division, Zomba, Nyasaland Protectorate, gives an account of Demodectic Mange of domestic animals in Nyasaland, and maintains that it is not economical to endanger the animals of the community by prolonging the life of infecting subjects, but that where treatment is considered desirable every possible precaution should be taken to prevent the disease spreading either by direct contact or through the medium of contaminated articles likely to come in contact with healthy animals.—A. Leslie Sheather, B.Sc., M.R.C.V.S., Research Laboratory, Royal Veterinary College, London, describes an improved method for the detection of mange acari dependent on the fact that these acari can be subjected to boiling caustic liquids without undergoing any outward alteration.—The general articles conclude with a revised check list of the animal parasites of domesticated animals in India by S. H. Gaiger, M.R.C.V.S., Indian Civil Veterinary Department, a list that from its size should be fairly complete. Several useful abstracts complete a most interesting number.

Dental Record.—The April and May issues of this journal contain a paper by Mr. J. F. Colyer on Dento-Alveolar Abscess and Dental Cyst. The paper is founded on a museum demonstration given at the Royal College of Surgeons last October, and forms an illustrated account of many of the specimens in the Odontological Section of the museum. The author shows that sepsis around the roots of the deciduous molars frequently involves the developing premolars, and in some cases leads to necrosis of those teeth. Some instructive specimens of palatal abscess are described, and attention is drawn to the large destruction of bone caused by these abscesses. The morbid anatomy of dental cysts is fully described, and illustrations are given of cases in which these swellings have encroached upon the antral cavity. There are over 50 illustrations.—In the May issue Mr. J. H. Mummery gives an account of his recent researches on tubular enamel, and comes to the conclusion that calcification commences in the prisms and then proceeds in the interprismatic material, and that the tubes run between the prisms and not in the centre of the prisms.—In both issues there are papers by R. Eckermann, of Malmö, on the etiology of caries.

MEASLES AT ST. AUSTELL.—At a recent meeting of the St. Austell rural district council it was decided to put into force the order of the Local Government Board for the notification of the first case of measles in every house. The medical officer of health has reported the continued prevalence of measles in the district.

THE LANCET.

LONDON: SATURDAY, MAY 29, 1915.

The Question of Conscription.

THE date of the statutory or religious holidays is very usually one against which we set in order our private affairs; and, whether we wish it or not, it is a date by which our attitude towards public matters is regularised. Instinctively we propose that one thing shall be done before the holidays, or that another thing shall be put off until after the holidays, and thus a great arrangement of business in an undefined and informal way goes on throughout the country round about these days of festival. The result is to find many people entering upon their work with renewed ardour after the holidays, not so much because they are physically refreshed, but because, in common phrase, they know "where they are." Whitsuntide found not only this country but the whole civilised world engaged in a contest of a sort that did not allow of this or that being put through hurriedly in order to get rid of the trouble by a certain date; still less do the conditions of war permit of any proceeding which is recognised as necessary being relegated to the future, however near; therefore it is in the nature of a coincidence that during the Whitsuntide holidays there should have occurred in the conduct of the war much the same kind of altered demeanour that characterises careful tradesmen who have estimated their commercial position upon the information gathered from a holiday stocktaking. And the coincidence has its value: it is a fact that the mind of the people has been prepared by the holidays for great alterations. Undoubtedly the nation is realising far better than hitherto "where we are." There has been of necessity a reviewing of the immense and terrible situation, and it is quite certain that the temper with which the war is to be carried on will now change in this country in a way that may surprise us all. There will be with us a more coherent idea as to the task that is before us and a more distinct apprehension of how the various calls on the national spirit and resources should be met. And the outcome of this change may be conscription, a measure of great medical significance in the circumstances.

Until quite recently there prevailed in this country a general and vague optimism. We remained under the influence of financial quidnuncs who said that the war could not last longer than the summer of 1915 because credits would be exhausted and supplies would not be forthcoming. Fortunately for the Allies no particular heed was paid to these prognostications, and preparations for a prolonged struggle were put in hand, though it is open to question whether they were undertaken with quite the necessary vigour—for which falling away from a strenuous ideal the said quidnuncs have to bear at least part of the blame. We were told, moreover, that the central European empires, cut off by our fleet from intercourse with the world, and suffering notably in East Prussia from interference with agricultural activities, would cease to produce the food-stuffs necessary for the support of the population, especially in view of the large waste which always occurs in time of war. No one who read the article published in THE LANCET upon the German reserves of food and their maintenance,[1] could have failed to gather that to speak of grave shortage of food-stuffs in Germany was quite premature. The possible position in Germany, in the case of British interference in the war, had been envisaged long ago by our enemy; precautions had been taken with the vigour and particularity that characterises all the German public actions, and we now know that the people who expected to find Germany hungry by the summer of 1915 were as wrong as those who expected to find her bankrupt at the same date. Gradually these things have been dawning upon the public, and it is very interesting to see how infectious the process of thought is. Within a very short space of time the public, which had so relied upon the optimistic prophecies of experts, passed into an unnecessary phase of gloom in which the resources of the Germans and Austrians appeared to be illimitable. Many of the journals of the country then began to represent this change of temper, and a deeper feeling of apprehension was produced which in some measure was as illogical as the previous attitude, based although that may have been upon ignorance. For while it is clear that the aggressive tactics which have marked our conduct of the recent stages of the war have not produced results commensurate with expectation, it is equally certain that the enemy must be far more disappointed with the position. And in one area the tide ran definitely against our cause; a great feeling of nervousness was produced, and the Government took stock of the situation. The result has been, we think, the production of the salutary impression that we must not deceive ourselves and the formation of a new administration representing the united will of a resolute people. Where we have been right we shall continue, and where we have been wrong we shall revise. Exactly at this moment, a moment which had been closely forecast by many, Italy enters the arena, marking a definite step in the progress of the war at the moment when our national temper required stiffening. It has compelled that rearrangement of ideas which is so particularly fitting to the holiday season. We see that attempts to make scapegoats for past blunders are not only ill-judged, but tragically wasteful of time; we fix our gaze on the future.

Medical men are perpetually engaged in clinical struggles where victory goes in the end to the therapeutists who, following now one indication and now another, may commit faults in technique. What, then, are most to be dreaded are futile recriminations; what, then, are most to be desired are a calm review of the position and reinforcement from expert advice. A section of the public are apparently willing to abuse those who have the charge of the conduct of the war on evidence of whose value they can know but little. We hope and believe that this unworthy tendency will die down, and that the example of Italy, which has thrown in its lot with the Allies in perfect knowledge that failure connotes national ruin, will strengthen, if this be needed, our determination to do all to bring this war to a speedy conclusion. How can we best show our Allies, who are aware at what cost and with what devotion we have already supported the common cause, that our future undertakings will be still larger, and will reflect more surely our dour decision to win? We have a new spirit upon us, and while on the one hand it should lead to an increased production of munitions, it is not so certain that it will increase our voluntary levies of men. The populace is waiting, we believe, to be released from the responsibility of initiative. Our military authorities think that it is absolutely necessary that we should have in training further large numbers of men to take the place of the heavy depletions which we cannot but expect. The remedy is surely some form of conscription, and with this procedure a medical journal would have no difficulty in finding itself in accord. We believe that some form of conscription would be for the good of this country at the present moment, and would serve both its mental and its physical health. No one knows better than the general practitioner how unequally the call for men to the colours has been responded to in different localities and among different classes. His peculiar knowledge of the population enables him to say for certain of any locality that some in it have gone to the war, quite enthusiastically, who should have formed the material for later drafts; and that others are still outside the army, when the army needs them, when they would make good stuff within its organisation, and when all that is required to secure their adhesion is to provide the method of making up their minds for them. Conscription would find strong support in the medical profession if it is advanced as a desirable measure in the existing circumstances.

---

◆

Flies and the Spread of Disease.

THE subject of spread of disease through the agency of flies has of late years met with a good deal of attention, and at the present time deserves careful consideration on account of the existence of a very large number of encampments in all parts of the country. Under the conditions of camp life in hot weather the influence of fly prevalence on the health of the occupants may be most important. If it is particularly with regard to the spread of typhus fever, enteric fever, and cholera that flies have been found to play an important part, it must not be forgotten that many other infections are disseminated by them, and that we do not really know the scope of their influence for ill. To the inhabitants not only of our own country but of the greater part of Europe the conveyance of disease by flies is for this coming summer a matter of very great moment. Every large European nation is more or less under arms, and the aggregation of huge bodies of troops in more or less temporary quarters inevitably brings about a state of things which encourages an increase of flies. The medical authorities in charge of encampments are well aware of the danger, and are not likely, in this country, to be careless in their measures against fly multiplication.

So far good. But for the ordinary town dweller special supervision and instruction as to his duty to his neighbour, as well as to his own household, may probably be advisable. The medical officer of health of Bermondsey carried on a systematic campaign against flies last year. A register was kept of all places where manure heaps or rubbish accumulations existed; about 20,000 handbills were distributed to householders, and posters were exhibited throughout the borough, explaining to the public what the danger was and what should be done to prevent it. Such a campaign might, we think, be instituted with advantage throughout the kingdom; in every camp where men are aggregated together in large numbers, with sanitary arrangements more or less temporary in character, steps should be taken to obviate the danger. The two main points to be kept in view are: (1) the removal of all rubbish, decomposing organic matter of any kind, and especially of excreta, from the immediate neighbourhood of the house or camp; and (2) the extermination, as far as may be possible, of flies of all kinds. With regard to the first consideration, in towns and places having a sewerage system there is no difficulty as regards immediate and complete removal of excreta and liquid refuse. Solid organic house refuse, which cannot be thrown into the drain, must be kept in covered receptacles and removed at frequent intervals. This is done by the local authority. Nevertheless, accumulations of manure and refuse heaps do exist, often uncovered, and are allowed to lie for days, forming breeding grounds for flies. Flies will not be attracted to a place, either indoors or out of doors, unless they find something to feed on. Of course, all articles of food likely to attract flies should be kept covered up, or within a properly protected and ventilated safe. The second point, the extermination of flies, presents several difficulties; but the principle to go upon is that of *obsta principiis*. The killing of adult flies, even in thousands, will not be sufficient; one must search for and destroy the eggs. If the campaign is taken in hand early enough in the season, flies that have survived from last year will also be dealt with.

The valuable reports issued by the medical officer to the Local Government Board during recent years should be in every hand, for all are interested in the matter of disease propagation by flies. Special reference may be made to Mr. J. P. Jepson's report on the breeding of the house-fly during the winter (New Series, No. 5; also Nos. 85 and 102 by Dr. S. M. Copeman); reports by several observers on the distribution of bacteria by artificially infected flies (Nos. 40, 53, and 66); and the reports on the range of flight of flies (Nos. 53 and 85). Professor A. E. Shipley states that house-flies usually begin to breed in June and July, and continue until October, being most active in August and September; but in warm stables or kitchens they may breed all the year round. The whole development of the fly, from egg to imago, may take place in nine or ten days; the second generation may lay eggs ten days later. We hope that the interesting Anti-fly Exhibition now being held at the Zoological Gardens, Regent's Park, London, a brief account of which appears elsewhere, will be visited by many responsible members of the public, who will thus be able to appreciate the measure of risk which a community runs through the evil-doing of flies, and will be prepared to second the efforts of our sanitarians to fight a very numerous and determined foe.

Annotations.

"Ne quid nimis."

THE IMMATURE SPIRITS (RESTRICTION) BILL AND MEDICINES.

As reported in our Parliamentary columns last week, the Chancellor of the Exchequer (Mr. Lloyd George) agreed to exempt rectified spirits used for the compounding of medicines from the provisions of this Bill. Representations on the subject were made by Mr. Glyn-Jones, M.P., Parliamentary Secretary of the Pharmaceutical Society of Great Britain, Mr. W. J. Uglow Woolcock, Secretary and Registrar of that Society, and Dr. Alfred Cox, Medical Secretary of the British Medical Association. As Mr. Glyn-Jones pointed out in Parliament, if medical men, pharmacists, and hospitals were not to be allowed to obtain rectified spirit by a prohibition clause in the Bill the position would become serious. The Pharmaceutical Society at once realised the situation, and urged that it is vital to the preparation of medicines that rectified spirits of wine should be available for use by registered medical men, hospitals, and pharmacists for the making of preparations of the British Pharmacopœia. In the recently published (1914) edition of the Pharmacopœia there are 427 preparations, and of these rectified spirit is a necessary ingredient in 263. Further, as the law stands it is absolutely illegal for anybody to make these preparations with anything but rectified spirits of wine. Subsequently general resolutions were passed, but the remissions did not appear because, as Mr. Lloyd George explained, it was not necessary to have a resolution for that purpose, all these matters, he added, being dealt with after the "charging resolution" had been adopted. Mr. Glyn-Jones was anxious that this matter should be made quite clear when the general provisions of the Bill were discussed, for as the resolutions stood they included all spirits. Mr. Lloyd George stated that it was the intention of the Government to exempt from these particular taxes the spirits used in medicine. The medical and pharmaceutical authorities, who strongly appealed for the exemption of spirit employed for medicinal purposes from the provisions of the Bill, have done excellent service to medicine by preserving the efficiency of dispensing practice in the directions indicated.

EGYPTIAN OBSTETRICS AS ILLUSTRATED BY A GREEK INSCRIPTION.

It is popularly believed that the process of child-birth among primitive peoples is a simple and comparatively painless one. There are signs that this is so, for some of the West African women at the present time make no ado whatever during parturition, all the circumstances being normal. But a difficult labour is a different matter, and if the assistance of a native doctor is called in the fate of the mother may be a terrible one. Where the knowledge of anatomy and medicine is very small the sufferings at complicated childbirth have always been terrible, and for many centuries they were just as great in Egypt and Greece, the most civilised countries of their day, as in the backward parts of Asia and Africa at the present time. A Greek inscription recently found in Egypt clearly illustrates this sad fact in the history of civilisation. It has been published by Professor G. Arvanitakis in the *Bulletin* of the Archæological Society of Alexandria, whose edition of the text may be thus rendered into English. "Who is the dead one? Herois. How and where? Having a tumour (ὄγχος) in the stomach. And, notwithstanding that we placed a weight (in the form) of Isis; the mother was lost very quickly, and then the child also. What was her age? Eighteen. So Herois was in the flower of her age. Oh, the unfortunate one. May Osiris render her ashes light and grant her sweet water." The story told in this record is one which, it is to be feared, was of frequent occurrence about the commencement of our era. Herois's first accouchement had arrived, and the doctor, or midwife, acting as attendant, finding the delivery delayed, proceeded by mechanical means to accelerate matters. He took a weight made in the form of a figure of Isis, a presiding deity on such occasions, and either placed it upon the mother's abdomen or, as is more probable, attached it by a cord to the already projecting part of the infant. In this case the mother would have been placed in a sitting posture, resting upon two stools, or standing erect. The erroneous practice in the case referred to produced the delivery of the child, doubtless injured, for it died shortly after the mother. The word translated tumour is ὄγχος, which Galen uses solely with that meaning.

PANCREATIC INFANTILISM.

"The characters of pancreatic infantilism are: arrested bodily and arrested sexual development; intelligence good, no mental defect; no deformity or structural defects of the bones; no visceral disease or derangement except chronic diarrhœa, flatulent distension of the abdomen, and defective or arrested pancreatic secretion. The defective or arrested pancreatic secretion is probably due to chronic pancreatitis. In some cases the condition (chronic diarrhœa and infantilism) is completely cured by the administration of pancreatic extract and by that treatment alone." In these words Dr. Byrom Bramwell defines the condition to which he draws attention in the *Edinburgh Medical Journal* for May. It appears to be extremely rare, although cases of arrested development associated with, and apparently due to, chronic diarrhœa are not so uncommon, but in these cases there is usually no evidence of defective pancreatic secretion. Dr. Bramwell records details of his case, which has been under observation off and on for 14 years, and has done excellently on pancreatic extract. He notes from the literature also four other cases, in all of which pancreatic extract gave most satisfactory results. It appears that there is also a type of disease, termed intestinal infantilism (Herter), which may simulate this pancreatic type, but in these cases there may be associated conditions such as anæmia and splenic enlargement, whilst in one case referred to there were gastric dilatation and severe gastric tetany. The indication of the true pancreatic infantilism appears to be found not only from careful tests, of which Sahli's appears to be particularly favoured by Dr. Bramwell, but apparently also by observing the effect of pancreatic treatment.

ATMOSPHERIC POLLUTION: INVESTIGATIONS IN MANCHESTER.

WE have received a copy of the first annual report of the Air Pollution Advisory Board of the Manchester City Council, from which it appears that the question is going to receive promptly a very thoroughgoing investigation in that city. In fact, the work of this board represents a very spirited attempt to deal with the problems of smoke abatement on new lines. In the monthly reports published in THE LANCET of investigations on the nature and amount of soot-fall those made by the authorities at Manchester have already been recorded, but their inquiries are about to be extended. Thus, in addition to soot-fall observations, actinometric and photometric methods have been tried, and also an air-filter. Systematic observations have been made by the use of (1) an iodine actinometer; (2) a photographic recording actinometer; and (3) a photometer for measuring daylight. Reference is made in the report to the soot-gauge returns published in THE LANCET. "They prove," the report states, "that for the month of October the total air pollution is less at Manchester than at Oldham, Birmingham, London, Sheffield, and Bolton, Oldham being much the dirtiest place. All of them contrast most unfavourably with Malvern, Oldham having about 28 times as much soot and tar as Malvern." The comparison in regard to Manchester and London is based on the results obtained at the Embankment station of the latter city, which has nearly always shown a much worse state of affairs than the other seven London stations. This evil condition is probably due to smoke from the river and railways. The comparison is hardly a fair one to use, therefore, in a broad generalisation. We are glad to see the progress that is being made towards carrying out systematic and scientific investigation of the atmospheric pollution created by smoke, and it is to be hoped that Manchester's fine example will be followed by other cities and towns. We are particularly gratified at the success of the movement since we took a large and active share in initiating it, and have from the beginning published the returns made in the monthly records.

THE CAUSATION OF GINGIVITIS.

GINGIVITIS, or inflammation of the gums, is most familiar in its chronic form, pyorrhœa alveolaris. Since attention was first directed to it the number of general medical and even surgical conditions which are held to claim oral sepsis as a leading etiological factor is very large; it appears to share with the large intestine the unenviable reputation of being a sort of slow poisoner through the machinations of the organisms it harbours. But whilst conditions in the colon can with difficulty be accurately investigated, the mouth affords readier access for this purpose, and sufficient facts have been adduced, we think, to make the physician very willing to seek the aid of the odontologist when faced with certain chronic conditions of probable infective origin. We know that the orthopædic surgeon has already appreciated the significance of oral sepsis in its relation to some arthritic states. It is probable, however, that, in turn, the physician may help the dentist, and this more especially in coming to a decision as to what is, after all, the essential problem—namely, the cause of the pyorrhœa. He may do so in two ways. First, gingivitis is a recognised sequela or symptom in certain general diseases. Some cases of secondary anæmia, for instance, lead to pyorrhœa by inducing an anæmic and flabby condition of the gums, and predisposing in this way to the entrance of organisms. In many cases of leukæmia gingivitis occurs; in measles similarly. Lead poisoning in its less marked forms may give a key to the true cause of an inflammatory or unhealthy condition of the gums, even in absence of the characteristic blue line. Scurvy, too, a primary blood condition, leads to changes in the gums. Secondly, it seems possible that gingivitis may follow dietetic errors. A recognition of such possible causes of lowered vitality, either general or local, is of much value. Generalised periodontal disease begins in a marginal gingivitis, and many dental pathologists consider that the latter condition is due to the formation of stagnant areas around the teeth. Dr. R. Ackerley, in an interesting communication,[1] considers that the main factors in producing the gingivitis are: (1) a chronic hyperæmia due to the habit of taking food and drink hotter than the body; (2) a chronic congestion of the mouth, throat, and nose due to hyperæmia of the stomach from overfeeding and too frequent feeding; and (3) the effect on the mucous membrane of the oro-pharynx of moist, warm, unwholesome, microbe-laden air. He states that he has seen several patients with considerable chronic gingivitis who were not mouth-breathers and who kept their teeth scrupulously clean, but who, on the other hand, were addicted to taking hot drinks. With the abandonment of the hot drinks he has found a marked improvement in the condition of the mouth. These observations emphasise the importance of the influences which certain foods, and the manner of eating them, exert upon the gums. Dryness of the mouth, induced by mouth breathing, leads to lowered vitality, as does also the sustained, chronic congestion of the gums caused by frequent drinking of too hot fluids, either in infancy or even in adults. In the former, such congestion may itself lead to mouth breathing. Of benefit are foods which demand considerable "gum exercise" or the act of sucking. Fat mixed with carbohydrates is to be deprecated because it makes a slimy film over the teeth, preventing efficient chewing. These are only some of the suggestions which a study of the mechanical value of certain foodstuffs offers. It would be of interest to follow up the possibilities of the effect of diet upon the gums. It is possible that a reversion to simpler fare or simpler cooking in certain directions may be found to result in general improvement in health, due not only to its effect upon the lower alimentary tract, but also to its improvement of the condition of the gums.

THE SPECIFIC GRAVITY OF THE HUMAN BODY.

THE specific gravity of the fluids and tissues of the body is one of the commonplaces of physiological data. The specific gravity of the body as a whole, important though it is in connexion with the power of the human body to float in water, is one which has received less attention, at any rate, in recent years. An interesting paper by Dr. C. D. Spivak, of Denver, dealing with this subject was published in a recent issue of the *Archives of Internal Medicine.* The earliest record of observations on the specific gravity of the human body which Dr. Spivak has been able to discover is that by John Robertson, librarian of the Royal Society, published in the Philosophical Transactions of 1814. Mr. Robertson undertook his experiments from the desire to know what quantity of timber would suffice to keep a man afloat in water, on the supposition that most men were heavier than river water. But his experiments showed that all the men he examined, except the first one, were lighter than an equal bulk of fresh water. Dr. Spivak has employed an ingeniously constructed tank with a gauge graduated in centimetres and millimetres to read off the level of the water within it. The individual to be examined enters the tank, and the level of the water is read before and after the immersion. The gauge was carefully calibrated in regard to the level of the water within it; the weight of water displaced by the individual could thus be determined easily. Dr. Spivak has also employed his method to determine the weight of the different parts of the body, reading off the level when the individual is immersed to the knees, to the arch of the pubic bone, and so on. In the case of a gain in weight he is therefore able to determine to what part of the body the gain has accrued. Dr. Spivak has taken the volumetric measurements of 14 individuals—namely, 4 adults, 3 males and 1 female, and 10 boys. The ages ranged from 53 years to 8 years, the weights from 79 to 26 kilogrammes, and the heights from 1·71 to 1·35 metres. All the measurements were taken at 7 P.M. before the evening meal. The specific gravity of the entire body varied between 0·976 and 1·049. The average specific gravity of the adults was 1·003 and of the boys 1·006, the average of all the individuals examined being 1·005. The other observations on record are according to Dr. Spivak either too low, such as those of Robertson, 0·8706; Suelzer, 0·970; Herman, 0·920; or too high, such as those of Krause, 1·055; Ziegelroth, 1·055; Miess, 1·012; Meeh, 1·012. Dr. Spivak maintains that his tank being of smaller diameter than any of the vessels hitherto used, is designed to get more accurate results than those of his predecessors. The difficulty introduced by the amount of air in the lungs is discussed by Dr. Spivak, together with the means of overcoming it.

THE NATIONAL INSURANCE ACT: THE REDUCTION OF CAPITATION FEES.

THE proposed reduction of quarterly advanced payments to practitioners on the panel formed a prominent subject of discussion at a conference at Chesterfield recently, a strong point being made as to the lack of evidence to justify the scale of reduction proposed. It was urged that this amounted to over 40 per cent., whereas the estimates of the Approved Societies with regard to enlistment pointed to an average of 12 per cent. withdrawn from insurance through military service. A resolution was moved and carried, "That this meeting of the Medical Alliance is of opinion that any deduction from the current accounts of doctors, chemists, or institutions exceeding 15 per cent. is more than is warranted by the circumstances, and trusts that where it may be necessary the Commissioners will give instructions for deductions not to exceed 15 per cent." At a meeting of panel practitioners convened by the Brighton members of the Panel Medico-Political Union the same subject was discussed, special stress being laid upon the responsibility of insurance committees for the present position of doubt and difficulty owing to their failure to institute and maintain correct lists. This is the point raised by Mr. C. W. Hogarth at the meeting of the London Panel Committee and commented upon in THE LANCET of May 8th, p. 982. Speaking at Brighton Dr. H. J. Cardale said it was impossible that the whole of the proposed reduction could be due to men joining the army, adding that the registers kept at the Insurance Committees' offices were probably to blame. In comment we would suggest that the framers of the Insurance Acts failed in their estimate of the enormous amount of clerical work and official verification which would be necessary if accurate working of the panel system was to be obtained. Hence the present unsatisfactory situation arising out of the same cause which brought into existence "unallotted funds."

THE EFFECTS OF ANTIMONY.

ANTIMONY is used as an alloy in a large number of articles, such as type, axles for machines, and cases of projectiles, and forms a constituent of certain glazes. From time to time an outcry makes itself heard as to the perils run by the workers in such trades on a par with that against lead poisoning. Professor E. Bertarelli, of Parma University, has lately investigated the hygienic conditions of workers in antimony in the Italian mines (*Il Morgagni*, March 22nd) and was unable to trace any special morbid condition, nor any particular or general form of poisoning amongst them. Although the suspicion might arise that workers in the antimony mines would be specially subject to anæmia, yet investigation showed that it was impossible to assert that the metal had acted in producing it. Neither among the workers in the sulphide were any cases of anæmia found which would suggest that antimony had any specific action in this respect. The trade which *a priori* would be considered most fraught with danger is the manufacture of antimonial glazes, which involves fine pulverisation of the metal or of its oxide or sulphide, as there is great probability of absorption by the skin or buccal mucous membrane. The author, however, found nothing among the workers in such a factory at Leghorn which would lead him to suppose that any poisoning took place. Nor were those forms of anæmia which certain observers have affirmed to be a common result of the absorption of antimony in industrial preparations met with in these workers, even though the most elementary precautions were neglected and the ingestion of small particles of antimonial substances must have been frequent. The conclusion seems to be that if antimony has any effect in causing anæmia or other morbid phenomena among workers it must be extremely slight.

INCOME-TAX RATES FOR THE YEAR 1915–16.

FOLLOWING on the articles in THE LANCET of April 24th and May 1st on "The Medical Man's Income-tax," and of May 15th on "Service Medical Officers and Income-tax," it may be useful to have the several rates of tax in concise form, which we extract from an explanatory article in the *Daily Telegraph* of May 25th:—

	In the £.
Normal Rate	2*s.* 6*d.*
Modified Rates:	
(*a*) Reduced Rates on Small Incomes:	
Incomes exceeding £300 but not exceeding £500	2*s.* 4*d.*
Incomes not exceeding £300	2*s.* 0*d.*
(*b*) Relief for Earned Income:	
Any individual who claims and proves that his total income from all sources does not exceed £2500, and that any part of that income is Earned income, to be entitled to be charged on his Earned income at the following rates, viz.:	
Total income not exceeding £1000	1*s.* 6*d.*
Total income exceeding £1000, but not exceeding £1500	1*s.* 9*d.*
Total income exceeding £1500, but not exceeding £2000	2*s.* 0*d.*
Total income exceeding £2000, but not exceeding £2500	2*s.* 4*d.*

It should be noted that the relief in respect of earned income is required to be claimed at the time a return is made, and in any case before Sept. 30th, 1915. It is supplemental to any relief under paragraph (*a*) above.

PULMONARY TUBERCULOSIS IN THE TROPICS.

IN the tropics it is the infectious disorders that cause the high death-rate among human beings, coloured or white. Van Loghem[1] draws attention to the increasing importance of pulmonary tuberculosis as a cause of death in tropical countries, and particularly in the Dutch Indies. The annual death-rate from phthisis in Amsterdam for the years 1900 to 1904 was 152 per 100,000 living, in London 163. The figures in subtropical and tropical towns are often much larger, as, indeed, is the general death-rate, and Van Loghem quotes the following figures: Havana, 348; Batavia, 409; Rio de Janeiro, 463; Manila, 486; Santiago, 492; Bombay, 635; Tunis, 691; and Singapore, 692, adding that they probably err by being too low rather than too high. The death-rate from phthisis among the whites alone is higher in the Dutch Indies than in Holland; for the years 1908 to 1911 it stood at about 125 per 100,000 living in Holland, whereas in Batavia it was 177, at Semarang 200, and at Surabaya 232. The cattle here are free from bovine tuberculosis, so that there can be no question of the infection of human beings with tubercle bacilli of the bovine variety. Stress is laid upon the fact that these figures only apply to the large centres of population, the coast towns, where the admixture of natives with civilised and tuberculous whites is most thorough. Inland the mortality due to phthisis, and indeed the incidence of any form of tuberculous infection, fall away to almost nothing. The cutaneous tuberculin reaction of von Pirquet, obtained in 92 per cent. of the students at Leyden by Nolen (1911), was obtained in only 3½ per cent. of the inland Javanese inhabitants of Sumatra (Heinemann, 1914), to quote a single instance. Thus, tuberculous infection during childhood is a rarity among natives uncontaminated by contact with a higher civilisation. The result, as Van Loghem points out, is that among such people tuberculosis is an acute infectious disorder very fatal to adults; for they have not been protected, as Europeans have, by a mild attack of tuberculosis during their youth. Heinemann describes tuberculosis as an acute or subacute disease, rarely chronic, among the uncontaminated Javanese, with a great tendency to the production of generalised tuberculosis such as it seen mainly in infants and young children in Europe. So Van Loghem calls out for some method of vaccinating natives against tuberculosis, and for the enforcing of all sanitary and hygienic regulations that tend to prevent the dissemination of tubercle bacilli, as two urgent needs in tropical countries where the native inhabitants are naturally free from tuberculosis.

EMETINE IN THE TREATMENT OF CHOLERA.

Sir Leonard Rogers reports the results of treatment of cholera by this drug in the *Indian Medical Gazette* (1915, vol. l., p. 4). No benefit can be derived from its use, he concludes. It was thought from the good results which follow its administration in amœbic dysentery, occasionally in sprue-like diarrhœa, and also in hæmoptysis and hæmorrhage from the gastro-intestinal tract, that it might be beneficial when there is, as in cholera, extensive loss of fluid through the mucous membrane of the small intestine. During an epidemic of cholera a series of 32 cases was treated with half a grain of emetine night and morning, in addition to intravenous injections of hypertonic solution of saline and potassium permanganate by the mouth. These cases were not selected; they were also compared with 32 similar cases which were taken alternately with the test cases but not treated with the emetine. The observations extended over two months. No benefit could be recorded. The whole mortality of the 64 cases was 12·5 per cent. A comparison of the two groups of cases showed the following features:—

	Emetine.	No emetine.
No pulse on admission	10	15
Blood specific gravity above 1065	8	3
Two or more intravenous salines	10	10
Age over 50	1	1
Deaths	4	4

THE Cavendish lecture of the West London Medico-Chirurgical Society will be delivered on Friday, June 25th, by Professor Arthur Keith, F.R.S., at the West London Hospital.

A SESSIONAL meeting of the Royal Sanitary Institute will be held in the Guildhall, Bristol, on Friday, June 11th, when a discussion will take place at 11 A.M. on "The Coördination of Military and Civil Sanitary Services in War Time," opened by Lieutenant-Colonel D. S. Davies, R.A.M.C. (T.), medical officer of health of the city, and Mr. L. S. McKenzie, A.M.I.C.E., the city engineer of Bristol.

THE USE OF ATROPINE IN THE TREATMENT OF THOSE SUFFERING FROM THE EFFECTS OF IRRITANT AND OTHER GASES.

BY DOUGLAS V. COW, M.D. CANTAB.,
BEIT MEMORIAL RESEARCH FELLOW.
(*From the Pharmacological Laboratory, Cambridge.*)

MY object in carrying out the series of experiments which form the basis of this communication is not so much to bring to light any new fact (the action of atropine on the bronchioles has been made clear by the experiments of Dixon and Ransom[1]), as to demonstrate in a clear manner the ways in which this drug may relieve the sufferings of those who have been exposed to the action of German gases.

From such information as I have been able to obtain it does not appear that atropine is being used to any extent in the treatment of these cases. I have therefore performed these experiments as rapidly as possible; and whilst taking account of the more obvious and gross changes produced, I have paid no attention to secondary conditions, such as the tension of various gases in the blood, the estimation of which would have taken more time.

From the symptoms produced by these gases it appears that some at any rate are irritant, the result being a condition in which the sufferer has a great difficulty in breathing and in efficiently oxygenating his blood.

Twelve rabbits were arranged in pairs according to their body weight, and were exposed to either chlorine or bromine vapour for periods of 15 minutes. Each pair was exposed to the vapour by enclosing the two rabbits together in a box (20 in. by 15 in. by 15 in.) with a zinc lining and a glass lid. The amount of chlorine given was that produced by adding 20 drops of hydrochloric acid to an excess of bleaching powder; the amount of bromine was such that the lower three inches of the box showed a thick yellow layer, whilst the rest of the space in the box appeared fairly clear.

As soon as the 15 minutes' exposure to the gas was complete the animals were removed to the laboratory (the box in which the gas was given was placed in the open air) and kept in boxes at laboratory temperature throughout the remainder of the experiments.

One animal of each pair was treated with atropine, the other being kept as a control. The dose of atropine given varied between 2·5 and 4 milligrammes, given in three, four, or five separate injections (the first injection in each case was intravenous, the others subcutaneous). In some cases the atropine treatment was started directly the animals were removed from the gas; in other cases the treatment was not commenced until 30, 60, or 120 minutes after removal from the gas.

Two pairs of the animals were also placed in a box through which a stream of oxygen was passed.

The results of the atropine treatment were very marked and agreed qualitatively throughout the series, though the effects were, of course, more obvious in some animals than in others. When removed from the gas the animals were in every case breathing with difficulty—head thrown back, nostrils working convulsively, and nose and mouth wet with inflammatory fluid. The rate of respiration at this stage varied between 92 in the worst case (chlorine) and 20 in the least urgent case (bromine), though in all cases respiration was laboured. The bromine animals were also very drowsy.

The condition became progressively worse; in about 30 minutes after removal from the gas stridor, crepitations, and rhonchi were evident; diminished resonance over the lungs was noted in one pair only (chlorine).

Atropine treatment affected the animals in the following ways:—the animals became more alert, respiration became much easier, less laboured, and more effective, the chest obviously filling and emptying more completely with each respiration than in the controls; the physical signs in the chest disappeared in every case except two, and in these two animals stridor and crepitations disappeared, a few rhonchi only remaining.

A particularly noticeable feature was the fact that of the two pairs which had oxygen treatment the two controls (which received no atropine) did not appear to be in any better case than other controls which received no extra oxygen; indeed, as it happened they were about the worst cases of the whole series.

The improvement in the animals which received oxygen as well as atropine was particularly obvious. After about an hour from the commencement of the treatment they appeared to be practically normal, though in most cases atropine alone seemed quite sufficient to relieve the acute symptoms.

The rate of respiration was not very greatly affected except in one case in which it was very much accelerated (92) before treatment commenced. This animal's breathing gradually came down to 60 half an hour after the first dose of atropine, and thereafter to 54, 52, and 50. The control animal of this pair, whose respiration was 66 on removal from the gas, continued to breathe at an average rate of 55 throughout. The only other case in which the rate of respiration was greatly changed was that of the other atropine and oxygen animal, in which the respiration came down from 22 to 14 per minute, the control in this case (oxygen only) falling only from 26 to 24.

All these animals were killed about five hours after the commencement of the treatment: the post-mortem condition of the lungs of the atropine animals as compared with the controls was most instructive. All the lungs from the atropine animals were normally collapsed (partially collapsed in the worst case), whilst in the case of the controls the lungs remained distended and retained the shape of the thorax like plaster casts after the chest was opened. A certain amount of frothy fluid exuded from the cut bronchi, the amount varying considerably, but always more in the controls than in the atropine animals.

Again the weight of the lungs showed marked differences as between the atropine animals and the controls; the average weight of the lungs from the atropine animals was 6·7 grammes, as against 7·9 grammes in the case of the controls, though the average body weights of the two classes were 1048 and 1036 respectively.

All the lungs floated in water: in three cases they were practically submerged: all these three were from animals which had received no atropine.

It is known from the work of Dixon and Ransom (*supra*) that so long as an animal is under the influence of atropine the bronchioles remain in a condition of maximal dilatation. The means whereby this drug relieves the symptoms, as described above, are sufficiently obvious to need no discussion. It remains, therefore, only to point out that without atropine oxygen inhalation produces little or no amelioration of the symptoms; that atropine treatment should be commenced as soon as possible; and that atropine in such doses as I have used should not be given to men, bearing in mind the fact that herbivorous animals have a peculiar tolerance to atropine.

---

[1] Dixon and Ransom: Journal of Physiology, 1912, xlv., 5, 413.

Atropine has the advantage over hyoscine and hyoscyamine in that the stimulant action on the central nervous system is more pronounced and the subsequent depressant action less in evidence than in the case of these other drugs.

ANNUAL REPORT FOR 1913 OF THE REGISTRAR-GENERAL.

IN a leading article in THE LANCET of May 8th we commented generally on the appearance of this report, which is the third of a new series inaugurated in the year of the recent Census. A change of form and of detail in these reports was required in order to give effect to the previously determined substitution of administrative for registration districts throughout England and Wales, the object being to coördinate conflicting areas for statistical as well as for sanitary purposes. The reasons assigned in favour of these and other subsidiary changes are set forth in the official reports for 1909 and 1910. Careful reading of the first volume of this series, which related to 1911, indicated the sufficiency of the precautions adopted for the preservation of continuity with the records of the past. Similar precautions have evidently been observed in preparing the present report. That the national records at Somerset House—essential as they are to due progress in public health—will in future be protected from ill-advised curtailment may reasonably be inferred from the exemplary attitude of the central authority to which reference has already been made.[1]

The present report, like its several predecessors, is the joint production of the Registrar-General and his statistical superintendent. The purely medical portion is contributed by Dr. T. H. C. Stevenson, who has again shown commendable care and skill in the conduct of the work.

We proceed to notice briefly those portions of the report that appear specially important from the view-point of preventive medicine.

Estimates of Population.

Inasmuch as the rate of natural increase of the English population has fallen since 1911, whilst there has been an increased loss of passenger movement, there is reason to believe that the rate of increase experienced in the last intercensal period has not been maintained subsequently. In no year previous to 1911 had a rate of natural increase been recorded so low as that of the last three years. The fall in the death-rate, which for a number of years had sufficed to compensate for the defect in the birth-rate, has now ceased to do so, and it seems likely that a period of definitely lower natural increase than in the recent past has now set in. To some extent this is due to the age constitution of the population. Since 1901, however, owing mainly to increased proportion of old persons among the living, resulting from fall in the birth-rate, the age constitution has become less favourable; and as this change progresses it will increasingly tend to raise the death-rate, and thus to diminish the natural increase. In view of the foregoing considerations it has been decided to frame the population estimates for future years on the natural increase of the living and the net effect of migration—the assumption upon which previous estimates were based having proved faulty. On the assumption of a continued increase, by geometrical progression, at the rate experienced in 1901–10 the population at the middle of 1913 is estimated at 36,919,339, but this number would have been reduced by 310,000 had the estimate been based on the natural increase and the migration returns.

Changes in Natality and Fertility.

Stated in terms of estimated population at all ages and of both sexes, the births registered in 1913 were equal to a rate of 23·9 per 1000, which is in defect of the average rate for the previous decennium by not less than 2·4. With the exception of the rate for the immediately preceding year, it was the lowest on record. Moreover, the provisional figures for 1914 indicate a still further fall of 0·3 per 1000. The birth-rate necessarily varies with the proportion of females living at conceptive ages, and with the proportion of these who are married. The changes in these proportions at the several censuses since 1871 are discussed in the text, and certain of these are specified as influencing the birth-rate, either by increase or by decrease. Among these changes may be noticed (*a*) the increased proportion of women of conceptive ages in the total population, which is a direct consequence of the fall in the birth-rate already recorded; (*b*) the varying proportion of women of fertile ages who are married; and (*c*) the increasing average age of married women under 45 years old. This appears to have been continuous during recent year, and must have contributed to the fall in the birth-rate, inasmuch as fertility is known to decrease with advancing age. As, however, our registers contain no particulars of the age of parents, nothing is known of the fertility of English women at the several ages. It is therefore at present impossible to determine the effect upon the birth-rate of increase in the age of potential mothers. The effect of decreases in the fertility of married women, due in some measure to their greater average age, but largely no doubt to deliberate restriction of child-bearing, is masked to some extent by the net result of other changes in the constitution of the population, so that the fall in the birth-rate cannot be fully accounted for.

Birth-rates in Different Localities.

In view of the impracticability of dealing separately with the statistics of the numerous administrative districts in the country, the Registrar-General in his recent reports has grouped the facts of birth (as well as of mortality) in "four geographical divisions," corresponding respectively to the north, the south, and the midland areas of England and the principality of Wales. The contents and limits of these areas cannot here be given, but they appear in the official reports of the last three years. In the summary tables of each division, the data for urban are distinguished from those of rural districts. Stated in terms of total population the highest birth-rate in 1913 was that of Wales, 26·9 per 1000, whilst the rate in the south of England was only 21·8. Moreover, if London were not included in the south the rate for that division would be lower still. The rate in the midlands was 23·6 and in the north 25·2. When different parts of the country are compared, Wales comes first, followed in order by the north, the midlands, and the south, whatever measure of fertility be employed.

Illegitimacy.

It has long been customary to measure illegitimate fertility by the proportion of illegitimate to total births, but by this method no satisfactory index is afforded of the fertility of unmarried women, which can only be correctly ascertained by comparing the illegitimate births with the number of possible unmarried mothers. The decline of illegitimacy appears to be considerably greater when measured by the latter method than by the former. In 1913 the illegitimate rate was equal to 7·9 per 1000 unmarried and widowed women, aged 15–45 years. Comparing the proportion of illegitimacy in that year with the proportion prevailing in the quinquennium 1876–80, it appears that, if based on the standard of total births, the rate of illegitimacy would seem to have decreased by less than 10 per cent., whereas the reduction will be found to equal 45 per cent. if calculated on the number of single and widowed women in the population. Relatively to unmarried women of these ages, illegitimate births were most numerous in the rural districts and least so in the metropolis. They were also most numerous in Wales and least numerous in the south of England. This is true of each of the three years 1911–13.

---

[1] THE LANCET, May 8th, 1915, p. 974.

Mortality in Relation to Sex, Age, and Locality.

The deaths registered in 1913 were in the proportion of 13·7 per 1000 living at all ages and of both sexes, a rate which is 1·2 per 1000 below the average for the preceding decennium. With the exception of that of the two previous years, the mortality in 1913 was the lowest on record. The standardised mortality of males exceeded that of females by 23 per cent. Since 1841–5 the mortality of females has fallen by 39·4 per cent., while that of males has fallen by only 31·5 per cent. The mortality of males is in excess at all ages except in the years of childhood, when mortality is at its minimum. The excess is very unevenly distributed, being large in infancy, negative in childhood, then gradually increasing to a maximum in later middle life, and subsequently declining again with advancing age. Up to the age of 35 for males and of 45 for females the mortality of 1913 was, at each period, only about half that recorded 50 years ago, but after these ages respectively the fall has been comparatively slight. For each of the four geographical divisions the rates of mortality are given in an instructive table. Presuming that the constitution of the population was less favourable to a low mortality in 1913 than in 1901, it is shown that although the effect of standardisation upon London and the smaller urban districts is only slight, the mortality of the county boroughs is increased by that process by 3 per cent., whilst that of the rural districts is diminished by 14 per cent., the contrast between them being thus greatly increased. As in the two preceding years the relative as well as the actual excess of mortality was least in the rural districts, whilst it increased with urbanisation to a maximum in London. Recent evidence therefore confirms the general impression that urban conditions tell more heavily on males than on females. The standardised death-rate of the north exceeds that of other parts of England. That of the principality is intermediate between the north and south, but in early adult life the customary tendency to excess of Welsh mortality over even that of the north of England still asserts itself. This tendency is more marked amongst females in the rural areas. The lowest mortality mostly prevails in the midlands and in the south.

Mortality of Infancy and Early Childhood.

Of the total deaths in 1913 those occurring in the first year of life amounted to 18·9 per cent., and were equal to 108 per 1000 births, a rate below the decennial average by 11 per cent. In different localities the rates varied from 131 in the northern county boroughs to 69 in the southern rural districts. The evil effects of residence in town as compared with the country are shown by the fact that the rate for the rural districts is exceeded by 41 per cent. by that of the county boroughs, but only by 20 per cent. in the case of London. The comparatively small excess in the metropolis indicates how largely the adverse influences of urban surroundings may be avoided. It is a noteworthy fact that the mortality of the County of London—the centre of the largest urban community known—was lower than that of England and Wales in the aggregate. Very remarkable is the geographical distribution of infant mortality; it was highest in the north of England and lowest in the south. Even the rural districts of the north are more destructive to infant life than is London, the excess being much greater in the male sex. It is interesting to extend comparison of infant mortality up to school age—i.e., to the end of the period of exclusively home influence. The range in the second year of life is greater than in the first. It varies from 14·5 in the southern rural districts to 50·8 in the northern county boroughs. The chances of survival in the second year of life in the latter are only slightly greater than those of the first year in the former. The causes of mortality in early life will be referred to later in dealing with the total loss of life from particular diseases. The mortality of illegitimate infants is about double that of the legitimate, the excess being greater among females. The mortality of illegitimate exceeds that of legitimate infants especially in the case of fatal syphilis, the loss of life from which infection is eight times as great among these unfortunates as it is among legitimate infants.

(*To be concluded.*)

THE ANTI-FLY EXHIBITION.

A VERY useful and practical exhibition, the Anti-fly Exhibition, was opened on May 13th at the Gardens of the Zoological Society in Regent's Park. This title is pregnant with the meaning of the exhibition by which it is intended to indicate that flies—the common house-fly among them—are not a mere nuisance but dangerous enemies to the race. Musca domestica, in the cause of ideal hygiene, must be fought with the same implacable determination employed in dealing with the malaria-spreading mosquito.

The Transmission of Infection by Flies.

The danger with which the public is not yet sufficiently familiar is rendered manifest immediately on entering the exhibition. A drawing of the common house-fly is suspended to the wall, well in view, which is so large in scale that the hairy covering of the feet and legs is seen, so that it can be readily realised that moist filth from any dustbin, gully, or midden can be taken up by a moving insect. Later, when partially dried, this filth may drop off perhaps on any foodstuff over which the fly walks, and the insect may have come in contact with the dejecta of a typhoid patient. The fly, moreover, is a very greedy beast, and will vomit undigested food so as to replenish its stomach with other food it prefers. The picture shows how by regurgitation specific germs previously consumed are brought up and ejected on the supplies in unprotected larders, while the insect, emulating the noble Romans of the days of Petronius, quietly proceeds to consume the better fare it has discovered. In this process a large bubble is formed outside the fly's mouth which we see in the drawing. Beneath the revolting and engrossing picture of the fly there is a series of beautiful models of the germs found by Dr. Birmingham in these bubbles coming from flies. These models, magnified to 1500 diameters, show that flies carry the germs of typhoid fever, tuberculosis, cholera, anthrax, and plague. Flies are also believed, on good grounds, to spread ophthalmia, dysentery, and infantile diarrhœa. After feeding on liquid or moist matter contained in excrement, wounds, sputum, decaying meat, fish, or other organic substances, they penetrate our larders and alight on our food. The extent to which disease is spread in this way cannot as yet be estimated, but we need not wait for blood-curdling statistics before deciding that the fly is a dangerous enemy to society.

Preventive and Other Anti-fly Measures.

Both the germs and the processes by which they are spread, so magnified that we can easily see and understand, are now exhibited. No one can plead ignorance after this object-lesson, and we are immediately led to inquire how so evident a danger is to be avoided. Naturally, the first step is to prevent flies from coming into existence. Where this can be done we have the most certain remedy. Therefore we are shown at the exhibition what are the favourite breeding-places for flies. They breed freely in every form of offal. Preserved in spirits, there are shown at the exhibition all sorts of offal and refuse—fishes' heads, putrid shell-fish, and kitchen débris—in which flies have laid their eggs. The first lesson, therefore, is that no moist offal should be allowed to remain near human settlements; it should be burnt, or buried, or transported where it can do less harm, if more radical methods fail.

At the Zoological Gardens there are devices for dealing with stable and farmyard manure, which provide the most extensive breeding-ground for flies. This has been demonstrated by a simple experiment. After flies have laid their eggs on a small heap of stable manure, if it is boxed over with wire gauze so that none of the flies can escape but must remain to multiply at their birthplace, the rapidity of their increase is demonstrated. And when we realise how quickly a plague of flies can be brought about, we only want to learn the methods of remedy to apply them with a will. A manure heap can be converted into a fly-trap with very little trouble. By placing round it at a distance of 12 inches a ring of dry straw the straw will quickly contain the maggots as they wish to pupate, and the straw is burnt every four days so as not to give the chrysalides time to transform themselves into flies. It is not always feasible to dig manure into the ground; it should always be kept dry, or be treated with an insecticide which may be superficially applied, and which will keep flies away, All these measures mean care, watchfulness, and trouble. The sprinkling of poisonous fluids, which can be used not only on manure heaps, but on walls, trees, and roofs, in the clearly indicated parts of premises, is a simple measure. One of the oldest methods of making fly-traps is also one of the best. It is to dip bunches of grass in a mixture of treacle or brown sugar impregnated with some arsenious salt, and hang them up in likely spots, taking care to place them beyond the reach of children. The use of poison, however, always involves some risk, and many will prefer the traps that catch living flies instead of poisoning them. From America we get an ingenious and very simple device called the Minnesota fly-trap. It is an oblong box of wire gauze. One side is bent inwards to form an arch, and at the apex there are several holes big enough to push a pencil through. The box is placed on the ground or on a shelf or table, the arch covering a bait such as a banana. A little room is left so that the fly may pass under the sides of the box and reach the bait. When satiated the fly goes upwards and finds its way through one of the holes into the portion of the box covering the arch. Here it will struggle to get out, but always by flying upwards and sideways and towards the light. It never thinks of going downwards to find the little hole by which it entered. Thus caught, the flies can be killed by dipping the trap into hot water or holding it over fumes of paraffin oil or benzine. This trap is shown at the Anti-fly Exhibition, together with other and more complicated traps. The Minnesota trap is the easiest to carry about and to make.

An Effective Insecticide.

Though war against the common house-fly and blow-flies or bluebottles is the main purpose of this exhibition, the danger of disease spread by insects generally is considered. The fact is illustrated that we have in crude mineral oil a cheap, easily obtainable, and applicable specific. Not only is it used to prevent mosquitoes breeding in stagnant water, but it can be made into an emulsion which will rid us of such pests as fleas. In war perhaps lice are the cause of our principal concern. In Serbia and Montenegro, and we fear in some of the German prisons or internment camps, they are spreading typhus fever. The work done in destroying flies by the English Commission has saved thousands of lives to our gallant allies. Professor H. Maxwell-Lefroy, with the assistance of Dr. Harriette Chick, of the Lister Institute, has issued a small pamphlet of instructions dealing especially with the use of crude oil, and 4000 lb. of crude oil emulsion have been sent to the soldiers at the front Anyone can make the emulsion. Five and a half pints of crude mineral oil with three pounds of soft soap and about half a pint of water will form a jelly that will prove an efficient insecticide. A more delicate preparation is exhibited at the exhibition made with "bottom" oil and Texas fuel oil, but the principle is the same. The vapour of the lighter oil kills insects, and the grease on the skin or in the clothes kills by contact. The soap makes it feasible to mix the emulsion with water and use it for ordinary washing purposes. If some of the emulsion is allowed to dry into the clothes vermin will not approach those who wear clothes thus treated. The same protection is secured by rubbing a little of the emulsion over the skin. During the war this is likely, one would think, to prove a most useful preparation. A few tins holding a grease or jelly that looks like soft soap are not interesting to look at, but when we realise the results that can be obtained by distributing these tins they gather importance in our sight, and the desire to send any quantity of them to the typhus-stricken towns and villages of Serbia and Montenegro, has been expressed by more than one visitor.

Everyone who can spare the time should visit the Anti-fly Exhibition.

Literary Intelligence.—Under the title of "Sanitation in War," the lectures by Major P. S. Lelean, assistant professor of hygiene at the Royal Army Medical College, with an introduction by Sir Alfred Keogh, are announced for publication about June 1st by Messrs. J. and A. Churchill. The subjects dealt with are: Physical Fitness for War, Anti-typhoid Inoculation, The March, Sickness in the Army, The Rôle of Insects in War, Field Conservancy, Medical Organisation and Administration in the Field, and Water and Water-supplies.

ASYLUM REPORTS.

Royal Albert Institution for the Feeble-minded of the Northern Counties (Annual Report for the Year ending June 30th, 1914).—At the time of its establishment, 50 years ago, the Royal Albert was the only institution of its kind in this part of the country, and since its opening it has dealt with no less a number than 3433 feeble-minded persons. It is satisfactory to note that at no time since its foundation has its financial and general position been higher or its prestige greater. Not only from its size and general equipment, but also from the results in educating and training the feeble-minded, the institution is second to none of its kind in the world. Mr. Archibald R. Douglas, the medical superintendent, comments on the passage of the Mental Deficiency Act of 1913, and says that about the future of the Royal Albert and the other kindred institutions there ought to be no doubt. From the fact of possessing a complete equipment of buildings and a full staff of teachers and manual trainers, these establishments are quite prepared and ready to act as training centres. Now is the time for local authorities and boards of guardians who do not wish to provide for their own feeble-minded to apply for accommodation to be reserved for their cases in these institutions. Another very important question for the consideration of the central committee in the near future will be the reception of children above the age of seven years sent by the education authorities.

The aggregate number of patients under treatment during the year was 807, with an average daily number resident of 696. An undesirable preponderance of those admitted have been low-grade and feeble cases. There were 65 discharges and 13 deaths, the death-rate on the average number resident being only 1·87 per cent. The farm colony has been in constant occupation since October last, and has proved itself to be a useful dependency of the institution. For the past year the schools have been conducted on a novel plan, which provides for purely educational work during the first half of the day, the afternoons being devoted to the new industrial occupations which have been already introduced and which were mentioned in the last report. This departure has succeeded beyond the most sanguine expectations and has infused fresh interest into the teaching staff and all concerned. The most important factor in this rearrangement is that it provides employment for the greatest possible number of patients. Already these new industrial occupations are almost self-supporting, since for the most part the receipts from the articles made have defrayed the cost of the materials used. Care has also been bestowed on the provision of simple kindergarten occupations for the large number who are incapable of learning anything more, and who would therefore be otherwise wholly unemployed. The Herbert Storey Industrial Schools and Workshops have been maintained in a high state of efficiency. The committee have added cloth-weaving to the list of trades taught here, and have introduced one of Hall's hand-power looms.

VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING APRIL, 1915.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 6·3 per 1000 of the population, estimated at 4,516,612 persons; in the two preceding months the rates were 7·4 and 6·6 per 1000 respectively. The lowest rates last month were recorded in St. Marylebone, Islington, Holborn, the City of London, and Camberwell; and the highest rates in Stoke Newington, Bethnal Green, Stepney, Greenwich, and Woolwich. The prevalence of scarlet fever showed a further slight decline last month; among the metropolitan boroughs this disease was proportionally most prevalent in Hammersmith, the City of Westminster, Stoke Newington, Stepney, Battersea, Wandsworth, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 2339 scarlet fever patients at the end of last month, against 3609, 2989, and 2514 at the end

of the three preceding months; the weekly admissions averaged 272, against 317, 324, and 278 in the three preceding months. Diphtheria also was slightly less prevalent than in the preceding month; the greatest proportional prevalence of this disease was recorded in Paddington, Stoke Newington, Bethnal Green, Stepney, Poplar, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1621, 1562, and 1362 at the end of the three preceding months, had further declined to 1223 at the end of last month; the weekly admissions averaged 136, against 160, 172, and 142 in the three preceding months. Enteric fever was less prevalent than in other recent months; this disease was proportionally most prevalent last month in Chelsea, Hampstead, Southwark, Deptford, and Woolwich. The Metropolitan Asylums Hospitals contained 60 enteric fever patients at the end of last month, against 50, 64, and 46 at the end of the three preceding months; the weekly admissions averaged 13, against 13 and 8 in the two preceding months. Erysipelas was proportionally most prevalent in Paddington, Hammersmith, Hackney, Shoreditch, Stepney, Poplar, Southwark, and Deptford. The 18 cases of puerperal fever notified during the month included 3 in Lambeth, and 2 each in Islington, Bethnal Green, Southwark, and Wandsworth. The cases of cerebro-spinal meningitis numbered 140, this disease being proportionally most prevalent in Kensington, Chelsea, Shoreditch, Southwark, Bermondsey, and Greenwich. The 10 cases of poliomyelitis included 3 in Islington.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations of the several boroughs. During the five weeks ending May 1st the deaths of 6776 London residents were registered, equal to an annual rate of 19·6 per 1000; in the three preceding months the rates were 19·6, 20·7, and 21·2 per 1000 respectively. The death-rates last month ranged from 12·8 in Lewisham, 15·1 in Hampstead, 15·7 in Stoke Newington, 16·8 in Wandsworth, and 16·9 in Hackney, to 22·1 in Bethnal Green and in Southwark, 22·5 in Battersea, 25·1 in Shoreditch, 27·4 in Bermondsey, and 27·7 in the City of London. The 6776 deaths from all causes included 841 which were referred to the principal infectious diseases; of these, 503 resulted from measles, 35 from scarlet fever, 50 from diphtheria, 182 from whooping-cough, 5 from enteric fever, and 66 from diarrhœa and enteritis among children under 2 years of age. The lowest death-rates from these diseases in the aggregate were recorded in Hammersmith, Hampstead, St. Pancras, Hackney, Holborn, and the City of London, and the highest rates in Fulham, Islington, Bethnal Green, Poplar, Bermondsey, Battersea, and Deptford. The 503 deaths from measles were 317 in excess of the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Kensington, Fulham, Chelsea, Islington, Poplar, Bermondsey, and Battersea. The 35 fatal cases of scarlet fever were 22 above the corrected average number, and included 5 in Islington, 4 in the City of Westminster, 3 in Lambeth, 3 in Wandsworth, and 2 each in Fulham, Stoke Newington, Poplar, Southwark, and Deptford. The 50 deaths from diphtheria were 17 in excess of the corrected average; this disease was proportionally most fatal in Holborn, Shoreditch, Bethal Green, Poplar, and Southwark. The 182 deaths from whooping-cough were 53 above the corrected average; the highest death-rates from this disease were recorded in Finsbury, Shoreditch, Bermondsey, Battersea, Deptford, and Greenwich. The 5 deaths from enteric fever were 3 below the corrected average number, and belonged respectively to Paddington, Islington, Bermondsey, Lambeth, and Deptford. The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in Paddington, Finsbury, Bethnal Green, Stepney, Poplar, Bermondsey, and Battersea. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases, excluding diarrhœa, was 110 per cent. above the average.

RATS AND THE PORT OF LONDON.—The number of rats caught at the docks and on vessels arriving at the Port of London in 1914 was 42,916. Of these, 2716 were subjected to bacteriological examination, but in no case was there any evidence of plague.

THE SUCCESS OF THE PROBATION ACT.—Mr. R. Wallace, K.C., in binding over a prisoner at the London Sessions on May 20th, said that over 90 per cent. of the prisoners bound over under the Probation Act never saw the inside of a police-court again, a satisfactory result on grounds both of morality and of finance.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments have been notified:—Fleet-Surgeon: R. T. Gilmour to the *Vivid*, additional, for disposal. Staff-Surgeons: C. R. Rickard to the *Topaze;* A. H. S. Richardson to the *Skirmisher;* A. La T. Darley and J. C. Bringan to the *Victory;* P. L. Crosbie and J. J. H. Rooney to the *Pembroke;* and A. C. W. Newport to the *Vivid*. Surgeons: J. P. Berry (Reserve) to the *Victory;* H. E. Perkins to the *Pembroke;* and G. B. Cockrem to the *Vivid*. Temporary Surgeons: T. M. Wood-Robinson to the *Black Prince;* W. Whitfield to the *Conqueror;* W. A. Bailey to the *Monarch;* A. T. R. Wollaston to the *Agincourt;* R. H. H. Newton to the *King George V.;* E. D. Granger to the *Centurion;* J. G. Nicholson to the *Albemarle;* H. Wilks to the *St. George;* A. H. Wear to the *Ajax;* G. M. Heiron to the *Africa;* and H. B. Padwick and J. Paxton to Haslar Hospital.

ROYAL ARMY MEDICAL CORPS.

The undermentioned are granted temporary rank whilst serving at the Edmonton War Hospital:—Dated April 20th: Lieutenant-Colonel: Spencer Mort. Major: William Benjamin Batchelor Taylor, Henry Martin Rashbrook, and David Morgan Hughes.

George Arthur Wright (late Lieutenant-Colonel, Royal Army Medical Corps, Territorial Force) to be temporary Lieutenant-Colonel whilst serving at the Military Hospital, Whalley (dated May 5th).

The undermentioned temporary Lieutenants to be temporary Captains:—Dated May 26th: Norman Black, late Captain, Singapore Volunteer Corps; and John Paton, late Captain, Royal Army Medical Corps, Territorial Force.

Captain John A. Hayward, having ceased duty with the British Red Cross Hospital, Netley, relinquishes his temporary commission (dated May 12th).

Edgar William Willett, late Surgeon-Captain, Volunteer Medical Staff Corps, to be temporary Captain (dated April 27th).

Lieutenant Ian Macdonald relinquishes his temporary commission on account of ill-health (dated April 29th).

Lieutenant Frank H. Rae relinquishes his temporary commission (dated April 28th).

To be temporary Lieutenant: Daniel McKinlay Reid (dated April 10th). Temporary Lieutenant Owen Richards to be temporary Captain (dated May 21st).

The undermentioned to be temporary Lieutenants: Dated April 24th: Joseph Henri Napoleon Felix Savy, Henry Adams, Colin George Shearer, James David Mackinnon, Alfred George Brown Duncan, Herbert Hampden Taylor, George Fleming, John Ross, William Fleming Stevenson, Thomas Holmes Scott, George Francis Clegg Walker, William Magner, Joseph Edward Judson, Thomas Battersby Jobson, Joseph Humphrey Jones, Godfrey Douglas Hindley, James Henry Edwin Davis, Thomas Clifford, Valentine Henry Blake, Alfred Reginald Roche, Maurice Gerald McElligott, Denis Victor O'Connor, Robert Bern Tydd Stephenson, John Rhodes Dickson, Sidney James Wareham, and James Johnston Abraham. Dated April 25th: Daniel Owen Twining, Arthur Lawrence Jackson, Everard Cecil Abraham, Wilfred Raffle, and Cedric Roland Denny. Dated April 26th: Edgar Taunton, Richard Harrison, George Todd MacLean, Geoffrey Andrew Bird, David Fleck, Caleb Thomas Hilton, Stanley Elder Humphreys, Williamson Rust Reith, John Sneed Bookless, Charles Forbes Harford, Stephen Veitch Telfer, James Smith, Alexander Cameron Renwick, George Loudon Neil, Gerard Edward Lockyer, John Kean, Robert Thomas Herron, Ernest Edward Frazer, Andrew Crawford, William Reginald Ward Asplen, and Richard Henry George Weston, from 15th (Service) Battalion, The King's (Liverpool Regiment). Dated April 27th: Charles Gordon MacKay, Cecil Claude Cragg, John Newbury Fraser Ferguson, John Menlove Bennion, Arthur Richmond, George McMullan, Alfred MacKenzie Clark, Reginald Frederick Yencken, Aubrey John Colby Tingey, John Roberts Pate, Charles Edwin Price, William Samuel Nason, and George Sefton Miller. Dated May 8th: John Jones. Dated May 21st: Francis Mark Farmer to be temporary honorary Lieutenant.

INDIAN MEDICAL SERVICE.

The services of the undermentioned officers are replaced temporarily at the disposal of His Excellency the Commander-in-Chief in India:—Major E. R. Rost and Major R. D. Saigol. Lieutenant-Colonel Selby Herriot Henderson has been nominated a member of the United Provinces Legislative Council vice Colonel C. C. Manifold, C.B., resigned. Lieutenant-Colonel J. Lloyd Jones, Assay Master, Bombay, has been granted two months' leave.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank:—Arthur C. Bateman, Edmond Robinson, and Charles A. Mason.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Northumbrian Brigade: Surgeon-Captain Robert A. Nesham to be Surgeon-Major.

1st Scottish General Hospital: The undermentioned to be Lieutenants:—Herbert John Adam Longmore, Douglas Wales Berry, and Cadet Cameron Macdonald Nicol, from Aberdeen University Contingent, Senior Division, Officers Training Corps.

2nd Southern General Hospital: Captain William Cotton is seconded.

1st Western General Hospital: Captain Keith W. Monsarrat is seconded.

South Midland Casualty Clearing Station: Captain James L. Joyce is seconded. Walter Mundy-Cox to be Lieutenant.

3rd London General Hospital: William Francis Bensted Bensted-Smith to be Lieutenant.

1st Southern General Hospital: Captain Albert Lucas to be Major. Major Otto J. Kauffmann to be Lieutenant-Colonel. Christopher Martin to be Captain, whose services will be available on mobilisation. Leonard Kirkby Thomas to be Captain, whose services will be available on mobilisation.

East Anglian Casualty Clearing Station: Richard Vincent Slattery to be Lieutenant.

1st East Anglian Field Ambulance: Lieutenant Laurence Henry Hutchins, from the 3rd East Anglian Field Ambulance, to be Lieutenant.

3rd East Lancashire Field Ambulance: Lieutenant Frank G. Prestwich, from Attached to Units other than Medical Units, to be Lieutenant.

1st Welsh Field Ambulance: Lieutenant John Clarke, from Attached to Units other than Medical Units, to be Lieutenant.

3rd Welsh Field Ambulance: Major John Livingstone, from Attached to Units other than Medical Units, to be Major.

1st Northern General Hospital: James Dunlop Lickley to be Lieutenant.

4th Scottish General Hospital: Willie Whitelaw to be Captain, whose services will be available on mobilisation.

3rd Southern General Hospital: Edward Walton Spencer Rowland to be Captain, whose services will be available on mobilisation.

2nd London Sanitary Company: To be Lieutenants: Arthur Errington Rayner and Lieutenant Arthur H. Savage, from 1st South-Western Mounted Brigade Field Ambulance.

1st London Casualty Clearing Station: Captain William S. Forbes, from the Unattached List for the Territorial Force, to be Captain.

Supernumerary for service with the Officers Training Corps: Temporary Major Archibald M. H. Gray to be Major.

Attached to Units other than Medical Units.—Surgeon-Major James P. S. Ward, from Devonshire Royal Garrison Artillery, to be Major. Captain Norman Maclaren to be Major. Surgeon-Captain Evan J. T. Cory, from the 5th Battalion, The Welsh Regiment, to be Captain. To be Lieutenants: Richard Payne Pollard and Charles Beresford Alexander.

VOLUNTEERS.

1st Cadet Battalion, The King's Royal Rifle Corps: Surgeon-Lieutenant William H. Davis resigns his commission (dated July 23rd, 1914).

DEATHS IN THE SERVICES.

Surgeon-General Arthur James Payne, I.M.S. (retired), on May 21st, at Onslow-gardens, London, in his 89th year. He attained the rank of surgeon-general in 1885.

ROYAL HOSPITAL FOR INCURABLES, DUBLIN.—Mr. G. Jameson Johnston, F.R.C.S.Irel., professor of surgery in the school of the Royal College of Surgeons, and senior surgeon to the Royal City of Dublin Hospital, has been elected consulting surgeon to the Royal Hospital for Incurables, in room of the late Sir John Lentaigne.

CATS AS A CAUSE OF DIPHTHERIA INFECTION.—An outbreak of diphtheria at the Stockwell Orphanage, in which, out of 68 cases, 1 proved fatal, has been traced to some infected cats in the Orphanage. The number of cases was larger among the boys than among the girls, which is accounted for by the fact that the boys, singularly enough, took more interest in the cats.

"Audi alteram partem."

"CHARCOAL" OR "BINDING" WIRE FOR DRAINAGE TUBES.

To the Editor of THE LANCET.

SIR,—The memorandum on the treatment of the bacterial infections of projectile wounds in THE LANCET of April 24th makes special point of drainage. Rubber tubes which are in general use have been found efficient in civil surgery, whence the need for long-continued drainage has almost vanished; but where free and constant drainage of infected wounds is necessary the rubber tube does not fully meet the need; its imperforate walls permit the exit of fluids through the lumen of the tube only. Occlusion of this sole exit may arise, at the inner end of the tube, where it is liable to be blocked by the wall of the wound itself, by the flattening of the tube from natural pressure of the parts and from bandaging, or by angles which result from bending of the tube within the wound, or from fenestrating and so weakening the tube wall. Were infected wounds always hollow and cyst-like, a rubber tube might effectually drain them; but in the commoner case of irregular wounds whose inner walls fall together the drainage effected by a rubber tube may be but little more than would result from the use of a solid rubber cylinder.

To permit of exit and lavage, and no less of entrance for air and flushing, not only must the opening of the wound be free, but the walls within must be kept from falling together and so suffocating each other. The largest rubber tube which may be introduced can but keep apart those particular portions of the wound walls on which it lies, whilst the more tubes introduced the greater the area of rubber to press upon the raw and so impede both the weeping from it as well as the air getting to it.

Amongst the alternatives to rubber tubes for drainage wire has been suggested, though but little used in the last 20 years. The use of wire in strands or hanks is effective by capillary action, but the use of wire in tubes of open coiled spirals has further advantages. Suitable wire is of soft iron known as "charcoal" or "binding" wire; it is made in all gauges down to as fine as a hair; such gauges as 22–25–27 are suitable for coiling up into tubes; the higher the gauge number the thinner the wire; such wire costs, say, sixpence a pound or less by quantity. Charcoal binding wire has practically no spring; it is very easily bent and retains immediately the given bend. Nothing is used in the manufacture of binding wire which can harm an infected wound. A wire drainage-tube can be made of suitable size, shape, and flexibility on the spot in a couple of minutes, with no more elaborate tool than a lead pencil or a walking-stick, and a wise thumb. The tube of spirally-coiled wire can be bent to the shape of the wound; the gaps between the coils allow free entrance and exit of fluids and air to and from the wounded surfaces.

The gauge of the wire selected, the circumference of the wire tube and the amount of extension given to the spirals regulate the strength and flexibility of the tube. For example, coil two feet of gauge 27 wire round a lead pencil, press the coils up neatly together on the pencil, so forming about half an inch of close wire tube of some 24 coils; withdraw the pencil and extend the tube to six inches, thus producing a tube of which the spirals are about a quarter of an inch apart; bend each of the sharp cut ends into a small closed eye and then turn back the eye itself into the lumen of the tube whence it cannot irritate the wound.

Spiral wire tubes can be rendered to any shape without the angling and occlusion which occur when rubber tubes are bent: such shapes as horse-shoe, squares, discs. The introduction of a wobbly spiral tube into a deep pocket is facilitated by mounting the wire tube upon a length of pliable lead or compo piping; the lead pipe, being bent as desired, is passed down inside the length of the wire tube and the open end of the lead pipe engages the eye at the further end of the wire tube. The extraction of a spiral-coiled tube from a wound may be facilitated by drawing on the end of the wire and at the same time twisting it a little in that direction which will coil the coils more tightly.—I am, Sir, yours faithfully,

Warwick-street, W., May 20th, 1915. FRANCIS H. POTT.

MENTAL TREATMENT BILL.

To the Editor of THE LANCET.

SIR,—The Early Mental Treatment Bill was "not proceeded with" on the day of its introduction, but I do not know that it has been definitely withdrawn; if not, there are several things in it that need explanation. In the first place, the title is misleading. The Bill does not propose to enact or legalise mental treatment, whether early or late. At first sight I took it to be a Bill to enforce matutinal treatment by Christian Science, and it occurred to me that a shorter and more appropriate title would be "Christians, Awake!" but it appears on perusal to be a Bill for legalising the temporary detention of persons in the early stage of mental disease.

I do not know, and I cannot learn from the text of the Bill, whether "nervous breakdown affecting the mental condition" and "mental breakdown" are intended to mean the same thing, or whether either or both of them mean the same thing as madness, lunacy, or insanity. Insanity was introduced as a euphemism for madness, but it has long gathered about itself the same implications, and is now as forbidding and stigmatising as madness itself. If nervous breakdown or mental breakdown is to be substituted for insanity it will very soon have precisely the same implications as insanity and madness and lunacy; but whether or not it means the same as these terms I think the Bill should make the meaning clear.

That the "mental condition" may be disordered without the disorder amounting to insanity is, or should be, a commonplace among those who treat mental disorders. There are very many mental disorders that are not insane, and such disorders are very frequent. Is this Bill intended to facilitate the treatment of such disorders? If so, it is unnecessary and uncalled for. Persons suffering from them can now legally "obtain residential treatment" without "being certified insane and sent to an asylum or hospital under the Lunacy Acts"—in fact, it would be impossible to certify them.

If, on the other hand, the Bill is intended to legalise the detention of insane persons under formalities less complicated, and safeguards not less assured, than those at present in force, there is much to be said for it; but whether this is or is not the intention should be made clear. No one but a German would lacerate unnecessarily the feelings of the unfortunate, but the intention of an Act of Parliament should be placed out of doubt, even at the cost of hurting people's feelings. If "nervous breakdown," "mental breakdown," and "mental disorder" mean insanity, they should be so defined in the Bill.

It is forgotten, but I think it should be remembered, that until the Lunacy Act, 1890, the procedure for placing a lunatic under control was much simpler and more ready than the procedure under that Act, and that during the 45 years that this simpler procedure was in force not one case of improper detention ever came to light. The Lunacy Act, 1890, was passed under the driving power of the popular feeling aroused by the attempt to place Mrs. Weldon under control as a lunatic. The attempt was not successful. Mrs. Weldon's liberty was not interfered with for one moment, but for the unsuccessful attempt the parties making it were very heavily fined, and some were ruined, by actions at law. That law thus proved its efficacy up to the hilt, and the plain lesson to be drawn from it was that no law could do more. However, in face of the fact that the existing safeguards had proved thoroughly efficient, public opinion demanded additional safeguards, and additional safeguards were enacted. These additional safeguards are not more efficient than the old—they could not be; but they have made the procedure for placing a lunatic under control more cumbrous, and more dilatory, and more difficult than it was before. The consequence has been that, whereas under the old law practically every lunatic whom it was desirable to certify was certified, and received all the benefits of the protective provisions of the law, under the new law a multitude of lunatics who ought to be certified are not certified, but are either at large, to the detriment of themselves, their families, and the public, or are illegally detained, or at least taken charge of, without any formalities or any legal safeguard.

If the opposition to what is miscalled the Early Mental Treatment Bill arises from an apprehension that it would facilitate the detention as lunatics of those who ought not to be so detained, it is misconceived and ill-directed. Its effect would be just the reverse. It is not true, as the memorandum of the Bill asserts, that "such patients can only obtain residential treatment if they are certified as insane and sent to an asylum." It is true that under these conditions only can they legally obtain such treatment, but, as has happened in so many other cases, the excessive stringency of the law has led to its evasion, and such patients do obtain residential treatment in violation of the law.

It is a mistake to suppose, as the memorandum seems to suppose, that nursing homes are deterred, by the need of certification, from receiving cases of mental disease. The ordinary medical and surgical nursing homes constantly do receive such cases, and do not recognise that the patients are certifiably insane until they become unmanageable or objectionable, and then the home is glad to get rid of a case that it is not fitted to undertake. The Bill will not, therefore, facilitate the treatment of such cases in the ordinary medical or surgical nursing home. What it will do is to legalise a half-way house between the free world and the lunatic asylum, a refuge from which many will return to the world without having to pass the portals of that unreasonably dreaded institution.

Anyone who is really concerned for the liberty of the subject, and does not merely cherish it as an obstructive fad, should work heart and soul for the passage of this Bill, and for the excision of the absurd clause which limits its operation to the period of six months after the conclusion of the war.

I am, Sir, yours faithfully,
Parkstone, Dorset, May 17th, 1915. CHAS. A. MERCIER.

THE MEDICAL DEFENCE UNION AND THE NATIONAL INSURANCE COMMISSIONERS.

To the Editor of THE LANCET.

SIR,—I see a letter in your last issue from Dr. A. G. Bateman, of the Medical Defence Union, stating that this body intends to challenge the right in the High Courts to surcharge practitioners who, in the opinion of their colleagues, represented by the panel committees, have prescribed extravagantly and improperly. As a member of the Medical Defence Union I shall strongly oppose any of the funds of that body being used for such a purpose. If Dr. Bateman had had the opportunity, as I have had, of seeing the extraordinary concoctions ordered by certain panel practitioners, the total disregard as to the cost, even when a drug with a similar therapeutic action is much cheaper, and the preference shown by some to drugs that are unknown to the general run of practitioner, and particulars of which are only to be found in advertisements, he would realise that it is absolutely necessary to have a check of some kind. In the insurance area of Bucks three-quarters of the doctors who prescribe are able to keep to the level of sevenpence per prescription, the other quarter are mostly at the eightpenny level and seldom above 1s.

Yet we know that in the London area the cost is much higher, and there is no doubt whatever in my mind that there are many men who are prescribing expensive medicines solely with a view of making the Act unworkable. If they succeed in doing so and have a State Medical Service they will only have themselves to thank for it.

It is sincerely to be hoped that an important body like the Medical Defence Union is not going to be captured by enemies of the Act.

I am, Sir, yours faithfully,
Buckingham, May 24th, 1915. ARTHUR E. LARKING.

DIFFICULT LABOUR AND DENTAL DEFORMITIES.

To the Editor of THE LANCET.

SIR,—I have no wish to enter into a discussion in your columns with Mr. F. Lonnon, but I should like to correct a false impression he conveys in his letter in THE LANCET of May 22nd that subsequent to his interviewing the mother of the patient my attention was attracted to the relationship of difficult labour to dental deformities. My interest in the question was long antecedent to the International Medical Congress. Still further, until Mr. Lonnon's letter appeared I was quite ignorant of the fact that he was working on the subject. I shall be grateful for any help from your readers, and I have no doubt that I shall be able to obtain sufficient material without Mr. Lonnon's help. Incidentally, I may say that in the case to which he has referred the condition was probably due to a developmental defect, and not to injury at birth.

I am, Sir, yours faithfully,
May 25th, 1915. J. F. COLYER.

THE ZEPPELIN THREAT: SURGICAL FIRST AID FOR THE METROPOLIS.

To the Editor of THE LANCET.

SIR,—With regard to the note appearing under this heading in your issue of May 22nd (p. 1104) it is important to remember that the work and organisation of the Committee of the Royal Society of Medicine, in consultation with and with the assistance of the War Office, deals chiefly with the East Coast from Dover to the Wash, and that it takes no responsibility for organisation in the metropolitan area, which is exclusively in the hands of the Commissioner of Police. Your notice suggests that certain steps suggested by the committee have been adopted and arranged for in the metropolis, but we have no knowledge that this has been done.

With regard to the metropolis, the committee has laid before the Commissioner a memorandum of suggestions for the organisation of surgical aid for London, but we have no right to assume that the Commissioner either heeded or adopted these suggestions. It has also provided the Commissioner of Police with a list of hospitals, infirmaries, and dispensaries willing to receive patients, and a map of London indicating the positions of these places, but the list did not include any extemporised emergency centres. Further, it has undertaken, if called upon by New Scotland Yard, to send surgeons, assistants, and anæsthetists to any point in the metropolitan area where their services are required, but only if summoned by the police.

We have no knowledge that copies of the map, which was prepared by Sir Rickman Godlee, Mr. Ernest Clarke, and Dr. H. Moreland McCrea, have been distributed to every police office, or that copies of the map can be supplied on demand.

Would you kindly allow me to add a personal note? You were good enough to say that the organisation has devolved upon myself, but this is only true in the limited sense that as honorary secretary of the committee I have endeavoured to the best of my ability to carry out its instructions. The Executive Committee, consisting of Sir Rickman Godlee, Bart. (chairman), Mr. C. A. Ballance, Mr. A. H. Cheatle, Mr. Ernest Clarke, Mr. E. M. Corner, Dr. J. C. Dunn, Mr. Edmund Owen, Mr. W. H. Clayton-Greene, Mr. G. J. Jenkins, Dr. Moreland McCrea, Mr. J. W. Thomson Walker, has been in every sense of the word a working committee, and has held numerous meetings here and at the private residences of its members, and the detailed work of arranging the list of receiving places, and corresponding with the officials has fallen almost entirely on Sir Rickman Godlee, the chairman of the committee.

I am, Sir, yours faithfully,
J. Y. W. MACALISTER.
Royal Society of Medicine, Wimpole-street, W.,
May 26th, 1915.

BAZETT *v.* THE LONDON INSURANCE COMMITTEE.

To the Editor of THE LANCET.

SIR,—This action was brought as a test action to raise the questions (1) whether "insuperable difficulty," such as the Committee alleges, is a legally justifiable answer—unless there is actual *physical* impossibility, uncontributed to by incompetence, and not merely *moral* impossibility aggravated by slack enforcement of provisions to meet it—to a demand for the carrying out of an Act of Parliament; and (2) whether, if such insuperable difficulties really exist, resignation and not statute-tinkering is not the only honourable course for persons—especially if salaried—to whom impossible duties have been assigned; and to maintain that the breach of agreements on such a plea cannot destroy the right to damages. Under this particular Act it was hoped to establish that no apportionment of money for a year could be an adequate substitute for assignment of patients, but that, if it were the only alternative available, it had to be done by no "pro rata" rule of thumb—as inequitable a method as could well be conceived—but on the same principles of doing the best for patients and equalising the remuneration of doctors as would have guided common-sense persons in the legal distribution; and to claim that, taking the original date without power of alteration, every man then on the panel had his right both to a voice and to a share. Mr. Justice Darling suggested a compromise, which I did not accept, to my personal detriment, because it would have compromised my position as fighting for *principles* for all and not for mere cash for myself.

I was defeated, apparently, on the extraordinary contention, upheld by the judge in spite of my protests, that the doctors' complying with every detail the Committee might choose to demand, although it could not be found either in the Act or the Regulations, was a condition precedent to the obligation of the Committee to carry out the assignment of the doctorless persons, and that at the same time the gross errors in the doctors' lists which the Committee have made by the thousand were of little or no import, though they largely contributed to the difficulty of the assignment. I have succeeded, therefore—if this is left where it stands and where I, unaided, must leave it, I regret to say—only in showing that it is as useless for doctors to invoke the aid of our Courts of Justice as it is for them to trust to the word of honour of Insurance Committees or to the sense of equity of the Commissioners or to the pledges of the Government.

I am, Sir, yours faithfully,

HENRY BAZETT.

St. Mary's-terrace, Paddington, May 21st, 1915.

"DIFFERENTIAL DIAGNOSIS, PRESENTED THROUGH AN ANALYSIS OF CASES."

To the Editor of THE LANCET.

SIR,—In the review of Dr. R. C. Cabot's book with this title, which appears in THE LANCET of May 22nd, attention has been called to the fact that in the first volume the diagnosis is definitely stated at the conclusion of the consideration of each case, but that the same plan is not adopted in the second volume. In Vol. II. the diagnosis is given in the table of contents against the number of the case which appears in the body of the book. This change was made deliberately at the express request of a large number of subscribers to Vol. I., who pointed out that with the diagnosis printed at the end of the case and frequently catching the eye it deprived the reader of the mental training in diagnosis obtained by logical reasoning and led to the solving of the problem with the answer as a basis.

We are, Sir, yours faithfully,

W. B. SAUNDERS COMPANY.

Henrietta-street, W.C., May 21st, 1915.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE subscriptions received during the week include a cheque for £250 from the Agent-General for South Australia, on behalf of the South Australian Belgian Relief Fund. The continuance of open-handed support from the Colonies is a most gratifying feature, and accords thoroughly with the noble national spirit which the outlying parts of the Empire have displayed in every regard since the war began.

A handsome donation has been sent by the doctors and pharmacists of the city and county of Cork. The local committee spent a little money in judicious advertisement, and the cheque received amounted to £116 11*s.* 10*d.*

THE WEEK'S SUBSCRIPTIONS.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, are as follows:—

	£	*s.*	*d.*
West London Medico-Chirurgical Society, proceeds from sale of tickets for Reception given on behalf of the Fund (per Dr. O. L. Addison, Hon. Sec.)	44	12	10
South Australian Belgian Relief Fund (per the Agent-General for South Australia)...	250	0	0
Dr. A. Graydon	1	1	0
Dr. Barrs (collected by)—

* This donation was credited last week in error to the Stewartry of Kirkcudbright.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments kindly contributed by the following donors since the publication of the last list:—

Dr. A. M. Ware, Queen's Gate Gardens; Mr. J. W. McVitie, Hove, Sussex; and Dr. H. J. Starling, Norwich.

Instruments should be sent to the Apothecaries' Hall, Blackfriars, E.C.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Retirements in the Indian Medical Service.

Surgeon-General G. F. A. Harris, I.M.S., the Inspector-General of Civil Hospitals, Bengal, has retired after many years' service in India. His departure means the breaking of another link between the old school of sahibs and the present race of administrators, and he was held in as high esteem by the Indian population as by the European community. Surgeon-General Harris's family has been associated with India since 1749, when his great-grandfather came to India with a medical commission and died in the Hon. Company's service. His own connexion with India has been long and varied. His work in Bengal dates as far back as 1882, with interludes of work in the Central Provinces, the Re-united Provinces, and the Punjab. Many of the improvements in the Calcutta Medical College, of which he was formerly the head, are due to his suggestions, and all the assistant surgeons and sub-assistant surgeons are under a debt to him for his active steps in improving their pay, position, and prospects.

The retirement from the service is also announced of Lieutenant-Colonel R. H. Elliot, I.M.S., the distinguished ophthalmologist.

Victoria Caste and Gosha Hospital, Madras.

The annual report of the hospital has been laid before a general meeting of the governors and disclosed an unsatisfactory financial position, for the budget estimate for the current year showed an estimated deficiency of nearly Rs.6000. The managing committee of the hospital, the Countess of Dufferin Fund Committee, have recently adopted measures with a view of increasing the income and decreasing the expenditure, among others the introduction of a gradual scale of fees according to means of patients in the general wards with an income of Rs.50 or more per mensem.

Small-pox in Darjeeling.

The sanitary authorities at Darjeeling have been recently concerned over sporadic cases of small-pox. Each case was immediately segregated, and fortunately the disease was stamped out before it assumed epidemic proportions.

St. John Ambulance Red Cross Gifts.

The Indian branch of the St. John Ambulance Association has despatched close on £50,000 worth of Red Cross gifts to the hospitals at the various fronts and has received many appreciations from various sources, one of which is quoted here. Lieutenant-Colonel W. G. Pridmore, I.M.S., who is in command of No. 5 Indian General Hospital, Alexandria, writes as follows: "Before I left Karachi with No. 5 Indian General Hospital 50 ten-bed units of Red Cross gifts were handed over to me by your orders. My hospital is now opened out and ready and I have been able to unpack nearly all the St. John Ambulance Association gifts. These gifts have been, and are, most useful. If those who have laboured to make them could sometimes see the delight which the gifts give the wounded men they would be fully repaid for their trouble. On behalf of the wounded who are being and who will be treated in this hospital, I thank you and the kind people who have laboured to provide them most heartily. The articles which have been especially appreciated are mufflers, Balaclava caps, socks, rezais, blankets, and cigarettes."

Military Assistant Surgeons.

The Government of India have sanctioned the following redistribution of senior military assistant surgeons on the old presidential lists: Bengal, lieutenants 14, captains 14; Madras, lieutenants 2, captains 4; Bombay, lieutenants 7, captains 6; total 47. The necessary adjustment in the existing number of senior assistant surgeons in each presidency will be carried out in due course.

The Inspector-General of Civil Hospitals, United Provinces.

His Excellency the Viceroy has selected Lieutenant-Colonel C. Mactaggart, I.M.S., Inspector-General of Prisons, United Provinces, for the appointment of Inspector-General of Civil Hospitals, United Provinces, in succession to Colonel C. C. Manifold, I.M.S.

A Church Missionary Society Officer for France.

Mr. Arthur Neve, of the Church Missionary Society's Hospital, Kashmir, has accepted a post on one of the base hospitals for Indian troops, and has sailed from Bombay to take up his temporary duties. His brother, Dr. Ernest Neve, will remain in charge of the hospital at Srinagar.

April 24th.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear in the casualty lists published since our last issue:—

Killed: Captain F. M. Bingham, King's Own (Royal Lancaster Regiment) 5th T.F.; and Lieutenant G. M. Chapman and Lieutenant G. H. Lunan, both of the R.A.M.C.

Died of Wounds: Major W. P. Dillon, No. 2 Canadian General Hospital; Captain G. C. Glidden (attached 10th Battalion Western Canada Regiment), Canadian Army Medical Corps.

Wounded: Lieutenant W. Kelsey Fry, Lieutenant W. A. Stewart, Lieutenant P. W. James (from gas), Lieutenant A. C. Perry (attached 2nd Battalion Sherwood Foresters—from gas), Lieutenant J. R. Marrack (attached 1st Monmouth Regiment, T.F.), Captain H. F. Panton, Captain E. A. P. Brock (attached 2nd Royal Irish Fusiliers), Lieutenant P. Cagney (attached 2nd Essex Regiment), Lieutenant W. T. Quinlan, Lieutenant D. G. Watson, all of the R.A.M.C.; Captain H. S. Hollis, R.A.M.C. T.F.; Captain F. C. Bell, Major G. S. Mothersill, both of the Canadian Army Medical Corps.

Prisoner: Surgeon-probationer W. W. K. Brown, R.N.V.R.

DEATHS AMONG THE SONS OF MEDICAL MEN.

To the list given in our last issue of the sons of medical men who have fallen in the war must be added Captain P. Beattie-Crozier, only son of Dr. J. Beattie Crozier; Lieutenant R. E. J. Thomson, eldest son of Lieutenant-Colonel S. J. Thomson, C.I.E., I.M.S. (retired); Second Lieutenant T. F. Stocker, R.E., elder son of Surgeon-Major E. G. Stocker, R.E.; Captain H. de B. Riordan, only son of Colonel W. E. Riordan, R.A.M.C. (retired); Lieutenant R. H. Ackerley, eldest son of Dr. R. Ackerley, of Llandindrod Wells; Second Lieutenant Sidney Blair, son of Dr. John Blair, of Wigan; Captain R. C. C. Campbell, son of Colonel R. N. Campbell, C.B., C.I.E., I.M.S. (retired); and Lieutenant E. J. M. Robertson, son of Dr. J. R. S. Robertson, of Hayling Island.

THE PROSTHETIC SURGERY OF WAR IN GERMANY.

A Swiss correspondent writes:—"Professor Stoppany, the Director of the Zürich Dental School, who has just returned from a long stay in Germany, has published an interesting account of the way wounds of the mouth and face are now being treated there. If their condition permits, soldiers suffering from injuries to the mouth or face are conveyed, he says, to Strassburg, where they are treated in a special hospital organised and directed by Professor Römer. After mentioning that a large proportion of the wounds received in the trenches are those of the mouth and jaw, Professor Stoppany proceeds: 'The hospital which exists at Strassburg is the first that has ever been organised in any war for the treatment of wounds of the face and jaw. The staff numbers 55, and all the work (including the cooking), which is done by the wives and daughters of the professors, is performed without fee. The hospital itself is divided into two sections. In the first a dozen dentists examine the teeth of the soldiers, extract, and make plates. This work is carried out at the cost of the military authorities, who adopt the very reasonable point of view that a soldier with defective teeth cannot be thoroughly efficient. The remaining section of the hospital itself comprises two subdivisions—the operating theatre and the department in which are made the prosthetic moulds destined to replace the bones or sections of bone sacrificed in the operation, and the surgical work is entirely done by dentists, most of whom have taken their medical degree. The wounded are photographed and radiographed on their arrival and photographed before departure, and these photographs and radiographs will constitute a collection of the highest scientific interest.'

At the moment when Professor Stoppany left Strassburg more than 200 soldiers were undergoing treatment there, and the results already obtained were almost marvellous.

One other and not the least interesting point: Professor Stoppany is convinced that, contrary to allegations made some months back, no 'dum-dum' bullets have been used against the German troops."

EMPLOYEES OF LOCAL AUTHORITIES AND THE ARMY.

The Local Government Board have addressed a circular letter to the local authorities, dated May 21st, in which they say that in their previous circular of March 11th the necessity was pointed out for economising labour to the greatest extent possible, and, where substitutes are needed, for engaging only men who are not eligible for the army or suited for the special occupations in question. While acknowledging that many local authorities have recognised the importance of applying a similar principle in cases where vacancies arise in offices and employments, cases have come under their notice in which men who are eligible for the army or for the special occupations referred to have been selected to fill such vacancies, although it might have been possible to make some other arrangement. The circular continues:—

> The Board accordingly suggest that, whenever vacancies occur, and it is unlikely that candidates suitable for permanent appointment who are not eligible for the army or for special work in connexion with the war can be obtained, the local authority should consider first whether it would be possible by a rearrangement of duty among other officers to avoid any fresh appointment during the period of the war; and that if this should be found impracticable they should endeavour to secure the services of any retired officer with the requisite experience who might be able and willing to act during that period, or failing this should engage persons temporarily who are not eligible for the army or the special occupations as recommended in the previous circular in the case of substitutes.

It is recognised by the Board that persons so engaged may not always possess the same standard of qualification as would be required in the case of permanent appointments, but it can be made clear to them when engaged that the employment is only temporary, and that permanent appointments made after the war will be subject to all the ordinary conditions.

RED CROSS WORK IN EDINBURGH: A RÉSUMÉ OF MUCH WORK.—At the outbreak of war the Edinburgh Committee of the Red Cross Society recognised the importance of strengthening its organisation. A meeting presided over by the Lord Provost was held in the Council Chambers, when the general committee was reconstituted, and the following seven adjuvant committees were formed, with their respective conveners:

Finance (Councillor John Harrison), hospital accommodation (Professor H. H. Littlejohn), equipment (Mr. H. M. Rush), personnel (Mrs. Maxtone Graham), work parties and clothing (The Dowager Duchess of Abercorn), Samaritan (The Marchioness of Linlithgow), and transport (Sir M. Mitchell Thomson, Bart.). The Lord Provost is now making a further appeal for funds, which are required for general purposes, and particularly in the equipment and maintenance of hospitals, the provision of materials for clothing, and the maintenance of transport for the sick and wounded. In Edinburgh and its immediate vicinity 750 beds have now been provided in hospitals organised and staffed by the Red Cross Society, and these hospitals have been largely equipped by the equipment committee. The donors of the houses converted into hospitals have supplied a considerable part of the equipment and much of the clothing needed. A large number of patients from the front have now passed through these hospitals since the war began, in addition to Territorials. The military—i.e., first line hospitals—are provided in the Edinburgh district, with the exception of the Dalmeny House Hospital, entirely by the War Office, without imposing any burden on subscribers to Red Cross funds. The provision of the auxiliary hospitals is, at the request of the War Office, left to the efforts of the Red Cross Society. The contributions by the committee to the Scottish Hospital at Rouen have hitherto amounted to £400 a month.

The work parties and clothing committee at 42, Frederich-street cut out large quantities of material, and arrange for this being made into garments. At the music hall workers receive gifts of clothing and other articles, and pack and distribute them, and also make garments for which at the moment there is special need. There have been sent abroad in this way to various hospitals 49,000 articles, to hospitals at home over 17,600 articles, and to the navy 1280 articles. This does not include medical stores. The Edinburgh Committee has provided for work abroad nine ambulances, capable of carrying 36 stretcher cases, and has sent to our French allies three motor ambulances for 12 stretcher cases. In addition it has arranged for the transport of the sick and wounded at home. Since the beginning of the war 12,010 patients have been carried by Edinburgh ambulances and motor-cars. 1263 patients have been naval cases, of which 85 were German prisoners, mainly from the *Maintz* and *Blücher*. From the hospital trains over 1500 patients have been taken to hospital, while to auxiliary hospitals 1400 have been conveyed. From the camps in the Edinburgh district 4600 patients have been transferred to hospital. For this work the transport committee has provided four motor ambulances carrying 14 stretcher cases. There have been given for the period of the war three others carrying eight stretcher cases, while 16 motor ambulances, carrying 34 patients, have been lent—a total of 23 motor ambulances, capable of carrying 56 stretcher or lying-down cases at a time. The cost of providing the ambulances and maintaining and altering the plant has been £6072. In addition to this motor-cars to the number of 200 have been lent to the Edinburgh Transport Committee for the purpose of conveying sitting-up cases, as they are termed, to and from hospital.

THE ARMENIAN RED CROSS AND REFUGEE FUND.—An appeal, signed by Lady Henry Somerset, Lady Frederick Cavendish, Viscount Bryce, and the Dean of Manchester, has been issued asking for immediate assistance for the above fund. The appeal states that there are now in the field 10,000 Armenian volunteers fighting with the Russian Army, who have been equipped and maintained by Armenians all over the world at a cost of £6000 per day. It is estimated that there will soon be between 20,000 and 25,000 Armenians in the field, and at present they have no medical man, and there are only five untrained Armenian ladies assisting as nurses. Fifteen medical students from Kieff have gone to their assistance, but there are no Red Cross appliances of any sort, and these are urgently needed.

The civilian population is also sorely in need of medical aid. There are 12.000 Armenian refugees at Sarikamysch alone to be provided for, hundreds of old men, women, and children having tramped there through the snow without shoes or stockings, these articles having been seized by the Turkish soldiers, who in many instances drove the wretched people out as they entered the villages where they were billeted. The Armenian Society, composed of British and American people, is administering the Red Cross and Refugee Fund free of all cost, while the British Consul-General at Moscow is coöperating.

Donations of money may be sent to the honorary treasurer, Mr. H. A. Godson Bohn, at 17, Holland Villas-road, Kensington, or to the honorary secretary, Miss E. J. Robinson, at 35A, Elsham-road, Kensington.

THE RED CROSS IN MONTENEGRO.—Montenegro is being served for military medical purposes by the Montenegrin Red Cross and by two hospitals of 100 beds each established respectively by the British Red Cross and the Russian Red Cross. The Montenegrin Medical Service has now also 24 medical officers and 22 medical students distributed to the hospitals (from 60 to 100 beds) at Cettinje, Rondno, Nikchitch, Kalochine, Podgovitza, and elsewhere. There are army ambulances at various stations. The needs of Montenegro remain very sore, for typhoid fever is rife, and the population has been added to by an influx of refugees from Bosnia and Herzegovina. More medical men are needed who are prepared to offer their services voluntarily, and funds are urgently required. Contributions may be sent to the Duchess of Rutland, 16, Arlington-street, W., or to Lady Parkington, 58, Green-street, Park-lane, W.

The Red Cross ambulances which have been presented by various towns to London are to be reviewed as a fleet in July by Her Majesty the Queen.

THE KING GEORGE HOSPITAL.—This enormous hospital, whose medical, surgical, and special personnel we have already published, was opened without formality on Wednesday last, patients being received in a certain number of wards which had been prepared. An urgent message having been received by the committee that the hospital was, as far as possible, to be made ready for the reception of sick and wounded soldiers by May 26th, the first batch of resident medical officers entered into residence by that date, and the two top floors and the kitchens were placed in working order. The labours of organisation during construction have been considerable, as industrial questions with the workmen have periodically arisen.

As the result of the notice in THE LANCET four of the five microscopes which were wanted for work in the wards have been promised, the donors being Dr. Noel D. Bardswell, Midhurst; Mr. M. C. H. Moberly, Winslow, Bucks; Mr. W. F. Mellersh, Wimpole-street, London, and Mr. F. W. Edwards, Stanstead-road, Forest Hill, S.E.

The department for electro-therapeutic and massage treatment is now under the charge of Dr. T. Grainger Stewart, physician at the Queen-square Hospital for Diseases of the Nervous System.

QUEEN MARY'S CONVALESCENT AUXILIARY HOSPITALS.—Lady Falmouth and Mrs. Gwynne Holford ask us to state that Roehampton House, near London, will shortly be opened as a convalescent hospital for sailors and soldiers who have lost their limbs in the war. Mr. J. Pierpont Morgan also has offered Dover House, almost adjoining, for the use of officers. These houses together are capable of accommodating about 300 cases.

The Queen has consented to the hospitals being named "Queen Mary's Convalescent Auxiliary Hospitals," and has given a donation of £200. The scheme has also gained the patronage of Queen Alexandra, who, in sending a donation of £100, expressed her delight that the subject she had very much at heart was being taken up.

A strong committee has been formed, and the following is the list of the consulting staff: Mr. Thomas Openshaw, Mr. Robert Jones, Mr R. C. Elmslie, Dr. Thos. J. Horder, and Dr. Theodore Thompson. At these hospitals the wounded who are admitted will be cared for until they have learned to use their artificial limbs, and are capable of taking up some employment, when, by working in conjunction with other societies, every effort will be made to fit the men to earn their living. Grants have been made to the hospitals by the National Relief Fund and the Red Cross Society, but a large sum is needed in addition for the equipment and maintenance. Communications and donations should be addressed to Mr. C. H. Kenderdine (marked Auxiliary Hospital), at St. Stephen's House, Westminster, who will be pleased to answer all inquiries.

Vacancies for Medical Officers.—We are asked to state that there are three vacancies for officers in the 2nd Line and two in the 3rd Line, South Wales Mounted Brigade Field Ambulance, the former of which will be going into camp at an early date. Particulars can be obtained from Lieutenant-Colonel Herbert Jones, The Barracks, Hereford.

There are also vacancies for medical officers (carrying commissions as lieutenants R.A.M.C. T.) in the 3rd (Foreign Service) Line 3rd East Anglian Field Ambulance. Enquiries and applications should be addressed to the Officer Commanding, 3/3 East Anglian Field Ambulance, Walthamstow, London, E.

There are also vacancies for five medical officers prepared to serve abroad in the 2nd and 3rd Line Welsh Border Mounted Brigade Field Ambulance. Pay and allowances as in the Regular Army, together with outfit and camp kit grants. Full particulars can be obtained on application to Officer Commanding, 2nd Line Welsh Border Mounted Brigade Field Ambulance, Lambton Park Camp, co. Durham.

Wounded Allies Relief Committee and Serbia.—The Wounded Allies Relief Committee has received a most satisfactory account of the typhus hospital at Kragujevac from Dr. Lauwens, the medical officer in charge, who reports that the building provided by the Serbian Government is spacious, clean, and in all ways suitable; that the unit has received the utmost attention from the Serbian Government; and that the typhus epidemic is already declining, a total of 20,000 cases in March having dropped in April to 12,000. He further relates the safe arrival of the committee's motor ambulance, to be used, at first, for the transport of infectious cases. The committee is shortly dispatching to Serbia, to the Kragujevac Hospital, four R.C.H. touring cars, for the transport of the wounded, and their comparative lightness will be of great advantage on the heavy Serbian roads. The committee also appeals to the British public to supply the Serbian sick and wounded with boots and overcoats. As the typhus epidemic is already on the decline, the Kragujevac unit will shortly be adapted for purely surgical purposes. Dr. Lauwens urgently asks for surgical instruments, dressing materials and bandages, disinfectants, iodine, &c. Gifts in kind should be addressed to the Committee at Sardinia House, Kingsway; money to the honorary treasurer, Mr. T. O. Roberts (manager), London County and Westminster Bank, 217, Strand, W.C.

Military Hospital Accommodation in Aberdeen.—For some time past negotiations have been in progress between the military authorities and the Aberdeen parish council with a view to the transference of Oldmill Poorhouse to the former, to be used at a hospital. The City of Aberdeen Territorial Association has now received instructions from headquarters to take over the Poorhouse, the parish council being allowed a certain period within which to remove the inmates. The Poorhouse was originally licensed to receive 967 patients, but by using sitting-rooms as wards it should be capable of accommodating over 1000 beds. It is calculated that the taking over of the institution will result in a gain to the Scottish General Hospital of some 550 beds.

The British Fire Prevention Committee and the War Emergency.—The following particulars show the work done by the British Fire Prevention Committee (8, Waterloo-place, London, W.) during the first nine months of the war. The committee's special fire-survey force of honorary surveyors have surveyed in detail 500 establishments taken over for war emergency work, including extensive groups of buildings, such as auxiliary military hospitals. In each case the honorary surveyors' reports, which are prepared on special lines and accompanied by sketch plans, serve as a basis for the detailed written reports to the authorities concerned prepared at the committee's London headquarters. A warning service has issued a large number of public "fire warnings" in the form of posters, over 25,000 of which have been issued to auxiliary hospitals at home, in France, in the Mediterranean, and in Egypt, as also translations in French, Flemish, Urdu, and Panjabi. The issue of posters involved not only a careful distribution with directions, but also resulted, as a rule, in correspondence on technical points. Authorities and public corporations receive the posters free upon written application to the registrar of the committee. "Warnings" have also been issued to factories and workshops engaged on Government supplies in respect to air raids. A special fire-service force has been organised by the committee, comprising ex-fire-brigade officers and firemen, and 200 firemen with the necessary appliances are available for mobilisation in sections within 48 hours. Calls upon this force have so far only been made to a moderate extent for fire patrols. The work in each department has been carried out by the honorary officers of the committee and a small clerical staff without materially interfering with the routine work of the organisation. The Committee have recently issued some valuable hints on fires arising from air-raids, and they may be warmly congratulated upon their public service.

Prohibited Exports. — The Privy Council, under its powers to supplement or vary, whilst a state of war exists, and on the recommendation of the Board of Trade, any Proclamation or Order dealing with goods for exportation, has prohibited the exportation to all destinations of crude coal tar, and to all destinations other than to British possessions and protectorates the following drugs and chemicals—magnesium chloride, oxides and salts of cobalt, oxalic acid, phosphorus, and all forms of aluminium.

St. Thomas's Hospital is preparing to enlarge the accommodation there provided for wounded and sick soldiers by 300 extra beds, which are to be placed in huts now under construction.

The Royal Insurance Company, Liverpool, and the Liverpool, London, and Globe Insurance Company have each presented to the Liverpool Civic League a fully equipped motor ambulance for the transport of wounded soldiers to the Liverpool hospitals.

Medical News.

Board of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow.—At examinations held recently the following candidates were successful:—

First Examination.—Robert Austin, Joseph Black, Apcar Galustian, Francis Xavier Hayes, Donald Leslie Henderson, Robert Alexander Chermside Pooley, Sidney Hill Waddy, and Robert Wilson.

Second Examination.—Philip George Bainbridge, Alexander Balfour Black, Donald M'Kenzie Black, James Calder, Jean M' Murray Crawford, Robert Phillips Crawford, Reginald Douglas Howat, William Jackson, Reginald John Thomas Malcolm-Gasper, Joseph Michaelson, Patrick Aloysius O'Brien, and Samuel Sloan.

Third Examination.—John Carden Bedwell, William Campbell Borrie (with distinction), Kaikhasru Sorabji Bhiwandiwalla, William Brown, John George Buchanan, Harry Ellison, Owen Glendower Evans, John William Irvine, William Paterson Hay Lightbody, James Young M'Lean, H. Morley, and Charles Edward Stuart Runciman.

Final Examination.—Frederick Arthur Vere Denning (with honours), John Walker, George Thomson, John Mellon Smeaton, Stewart Newnham Toulmin, Wilson Thabo Mongoli Sebeta, Victor Albert Goonetilleke, John Scott, William Pigg Over, and Thomas Ross Scott.

Society of Apothecaries of London.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—C D. Banes (Section II.), King's College Hospital; A. U. L. Bennett (Sections I. and II.), Royal Free Hospital and Birmingham; H. A. De Morgan (Sections I. and II.), Middlesex Hospital; C. S. Dodson (Sections I. and II.), University College Hospital; J. C. Lee (Section I.), McGill, and L. N. Lee (Section II.), Geneva; H. B. Padwick (Sections I. and II.) and M. C. Stark (Section I.), London Hospital; and T. J. Thomas (Section I.), King's College Hospital.

Medicine.—W. Bailey-Thomson (Section II.), Aberdeen; J. A. A. Boddy (Section I.), Manchester; A. Butterfield (Section II.), Durham; W. Fox (Section II.), Charing Cross Hospital; J. C. Lee (Sections I. and II.), McGill; W. F. Matthews (Section I.), King's College Hospital; S. Rawlinson (Sections I. and II.), Manchester; and A. H. Taymour (Sections I. and II.), Guy's Hospital.

Forensic Medicine.—L. M. Arnold, Cambridge and St. Mary's Hospital; A. Z. Abushady, St. George's Hospital; L. S. Goss, Middlesex Hospital; J. C. Lee, McGill; I. H. Lloyd, Westminster Hospital; A. H. Taymour, Guy's Hospital; and T. J. Thomas, King's College Hospital.

Midwifery.—L. M. Arnold, Cambridge and St. Mary's Hospital; A. Butterfield, Durham; F. W. Chamberlain, Middlesex Hospital; K. M. Dyott, London Hospital; and J. C. Lee, McGill.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: C. D. Banes, A. U. L. Bennet, C. S. Dodson, L. N. Lee, H. A. DeMorgan, and H. B. Padwick.

Royal College of Surgeons of Edinburgh.—At a meeting of the College held recently the following gentlemen were admitted Fellows:—John Coffey, L.R.C.S. Edin. (triple qualification), Dublin; Norman Grenville Walshe Davidson, L.R.C.S. Edin. (triple qualification), Wolverhampton; Andrew Graham, L.R.C.S. Edin. (triple qualification), China; Garnet Reginald Halloran, M.B., Ch.M. Univ. Sydney, London; George Laurence, M.R.C.S., L.R.C.P. Lond., Chippenham; Joseph Currie Lorraine, M.B., Ch.B. Edin., Burma; and Vernon Laurie Miller, M.D., C.M. McGill Univ., Halifax, Canada. The bronze medal and microscope presented to the College by Colonel William Lorimer Bathgate, in memory of his late father, William McPhune Bathgate, F.R.C.S. Edin., lecturer on materia medica in the Extra-Academical School, was awarded, after the usual competitive written examination, to Mr. James Hood Neill, Edinburgh.

Royal Medical Benevolent Fund.—At the last meeting of the committee 15 cases were considered and grants amounting to £104 voted to 12 of the applicants. The following is a summary of the cases relieved:—

Daughter, aged 59, of M.R.C.S. Eng. who practised at Liverpool. Until the war broke out managed to earn a living as a teacher of singing, but practically all her teaching work has ceased. Has an invalid brother partly dependent on her. Voted £10 in two instalments.—Widow, aged 52, of M.B. Aberd. who practised at Watlington, Oxon. Left totally unprovided for at her husband's death after a long illness. Has one son who is an invalid. Relatives allow her £5 per month, but this is not sufficient to provide all that is required for herself and son, and applicant unable to work. Voted £10 in two instalments and referred to the Guild.—M.R.C.S. Eng., aged 77, who practised at Manchester and Brighton. Has been in failing health for some years, and is partially blind and suffering from right hemiplegia. Only income the Old Age Pension. Has one daughter, who has had to give up her situation to nurse her father. Voted £18 in 12 instalments, and referred to the Guild.—Daughter, aged 60, of L.R.C.P. Edin., who practised at Cheadle, Cheshire. Health very indifferent and unable to undertake regular employment. Only income £30 per annum. Relieved nine times, £76. Voted £12 in 12 instalments.—Daughter, aged 64, of M.D. St. Andrews who practised at Dover. Has a sister and niece dependent on her. Resides at seaside town and takes in paying guests but recently had difficulty in obtaining them. Relieved once, £10. Voted £10.—Daughter, aged 64, of M.R.C.S. Eng. who practised at Derby. Health very indifferent for many years. Only income £5 per annum from a friend. Lives with a sister who provides her with a home. Relieved five times, £60. Voted £12 in 12 instalments.—Daughter, aged 66, of M.R.C.S. Eng. who practised at Durham. Has been an invalid for years and unable to leave her bed and practically blind. Only income a pension from another charity. Relieved three times, £30. Voted £5.—Wife, aged 49, of M.R.C.S. Eng. Deserted by husband. Has one daughter, who was a governess, but has lost her employment in consequence of the war. Applicant very delicate. Only joint income recently 10*s.* per week. Relieved twice, £14. Voted £12 in 12 instalments.—Widow, aged 68, of M.R.C.S. Eng. who practised in Jamaica. Has three married sons, but none able to help. Only income £26 per annum from another charity. Too old to work. Relieved twice, £20. Voted £12 in 12 instalments and referred to the Guild.

Also three emergency grants of £1 each pending further inquiries. Six additional annuitants at £20 each were also elected, making the total number 148. Subscriptions may be sent to the honorary treasurer, Dr. Samuel West, 11, Chandos-street, Cavendish-square, W.

Mr. Neil McLeod, who died suddenly at his residence, Whitehall, Drighlington, near Bradford, on May 12th, was the medical officer and public vaccinator for the fourth district of the North Bierley union, and had a large local practice.

Parliamentary Intelligence.

HOUSE OF COMMONS.

Thursday, May 13th.

The War and Elementary Education.

Sir Henry Hibbert spoke of the excellent results obtained from the medical inspection of elementary school children. He was afraid that that inspection might have to be stopped or greatly curtailed during the war. In his own county (Lancashire) there was a permanent staff of 13 doctors, of whom 10 had gone to the war, Three of them were serving under the Serbian Government. Two other medical men on their staff were going, and that would leave them with one. They had 26 nurses and 18 had gone. They expected two to go almost any day. He did not see what, could be done in the matter because it was absolutely impossible to engage fresh medical men.

Dr. Addison (Parliamentary Secretary to the Board of Education) said that the Government now contributed a share to the medical inspection of school children, whereas formerly the cost fell upon the local authorities. Many authorities were now working with greatly reduced medical staffs. As to the use of schools for military hospitals, he had been round the country with a committee making provisional arrangements. In Liverpool and other places they visited with the local authorities all available buildings which were anything at all likely to be suitable, and their anxiety was to spare school children from dislocation and disturbance where possible. It had been suggested that chapels should be used for hospitals. A chapel was very seldom a suitable place. A place was wanted where a man lying on a bed could see out of the window and get a glint of sunshine, and it often happened with chapels and halls and such-like buildings that they only had windows high up, so that a man lying on a bed in the middle of the floor would see the light come in from above. Such buildings would not make suitable hospitals. All these considerations had been taken into account, and it was not with any avidity that the Board of Education consented to the use of schools as hospitals. It was found advisable by the Army Council to have a committee on this matter, and make a comprehensive scheme in case great numbers of beds were needed. The various local authorities coöperated with the committee in every way, and it was found quite possible by friendly negotiations in all the great cities visited to arrive at a scheme, and, notwithstanding the criticisms from outside, arrangements were made which he thought would be found to meet the full requirements of the case and cause as little disturbance and friction as possible. Arrangements for 1500 beds could not have been made without disturbing someone.

Mr. Pease, replying to a question relating to physical education, said that the Board of Education had recently had appointed two or three extra inspectors in connexion with physical training, men who had studied the subject and had passed tests in Sweden or elsewhere, to go round the country and see that the best system of physical training was adopted in schools. They were to examine the curriculum of the school and to see that as much attention as possible, having regard to the other interests of the school, was given to physical training and exercise. He believed that more could be done, especially in connexion with the first few minutes of the school day. In many of the schools the first ten minutes were given to breathing exercises and to certain simple exercises in addition to the regular period set apart of from 20 to 40 minutes for physical training. A real advantage would thus be secured by the children. Physical exercise was being made a compulsory subject in all the training colleges.

Wednesday, May 19th.

Consulting Surgeons' Service with the Army.

Mr. Joynson-Hicks asked the Financial Secretary to the War Office whether the following surgeons, Sir G. H. Makins, K.C.B., Sir A. A. Bowlby, C.M.G., Mr. F. F. Burghard, Mr. W. T. Lister, Mr. H. M. W. Gray, and the following physicians, Sir W. P. Herringham, Sir A. E. Wright, Sir J. R. Bradford, and Sir B. Dawson, K.C.V.O., were employed at the front at ordinary Royal Army Medical Corps salaries; and whether he had any difficulty in getting eminent doctors to serve in consulting positions either abroad or at home at the ordinary rates of pay given to the officers of the Royal Army Medical Corps.—Mr. H. Baker replied: The officers named are employed at the front with pay as colonels of the Army Medical Service, and so far there has been no difficulty in obtaining eminent medical men to serve in consulting positions either at home or abroad at the rate of pay offered.

Medical Men and War Service.

Mr. Ginnell asked the President of the Local Government Board to state the number of medical officers of local administrative bodies in England and Wales who had volunteered for service in the present war, the number of them serving, and the treatment of them by those bodies generally in regard to continuance of salary, payment of substitute, and keeping their positions vacant for them.—Mr. Herbert Samuel (in a written reply) answered: The number of medical officers of health serving with the naval or military forces, so far as the Local Government Board know, is 171, and the number of tuberculosis officers and assistant tuberculosis officers so serving is 52. I have no information as to the number of officers who have volunteered but are not serving. A large number of assistant medical officers of health, superintendents of isolation hospitals, Poor-law medical officers, and school medical officers are also serving. Generally speaking, local authorities pay such officers during their absence the difference between their civil pay and their navy or army pay, keep their positions vacant for them, and appoint temporary substitutes where necessary.

Mr. Ginnell asked the Chief Secretary to the Lord Lieutenant a similar question in regard to the medical officers of local administrative bodies in Ireland.—Mr. Birrell furnished the following written reply: About 26 or 27 Poor-law medical officers have been granted leave of absence to join the Army Medical Service. Their positions will be kept open for them. In some cases the guardians are paying the medical officer his salary and also paying the substitute. In others the salary is paid to the temporary substitute only.

Disabled Soldiers.

Replying to Mr. Ellis Griffith, Mr. H. Baker (Financial Secretary to the War Office) wrote: A wounded soldier considered to be permanently unfit for further service is brought before a medical board, and may be discharged from the service before complete convalescence is attained. He can, however, remain in hospital as a free patient until it is considered advisable that he should leave, and during this period he draws any pension or disability pension awarded him. All insured soldiers while suffering from disability are entitled on discharge from the service to full benefit under the National Insurance Act, except that, as provided by the Select Committee on Pensions, sickness and disablement benefits are reduced by 5*s*. a week for men who are drawing the total disability pension at the new rate.

National Insurance Payments to Medical Men.

Mr. Bridgeman asked the Chancellor of the Duchy why it was that medical men were not paid each quarter the full amount due to them under the National Insurance Act; what means doctors had of recovering arrears due to them; and why in the border parishes they received mileage pay on the Welsh side but not on the English side for patients distant more than three miles.—Mr. Montagu wrote in reply: In answer to the first part of the question, the remuneration due to practitioners on the panel under their agreements with Insurance Committees is ascertainable annually and not quarterly. The quarterly payments are advances on account of remuneration which cannot be determined until the close of the year, and no quarterly settlement is therefore practicable. As regards the latter part of the question, the distribution of any mileage grant among the doctors in any particular area is largely a matter for the doctors themselves. If, however, the honourable member has in mind any particular case, I should be pleased to make inquiries.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Boycott, Arthur E., M.D. Oxon., F.R.S., has been appointed Director of the Graham Research Laboratory.

Ewan, J. A., M.D. Edin., has been appointed Temporary County Medical Officer of Health for Kesteven.

Gemmell, A. C., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer to the Red Cross Hospital, Ampton Hall, Bury St. Edmunds.

Jones, Peter, M.D. Edin., has been appointed Medical Officer of Health for the Abergele and Pensarn Urban District.

Kelleher, T. A., M.B., B.Ch. R.U.I., has been appointed Temporary Medical Officer of Health to the Waterford and New Ross Port Sanitary Authority.

Shorland, W., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for Briton Ferry and Baglan Lower.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

Birkenhead Borough Hospital.—Female Senior and Junior House Surgeons. Salary £180 and £150 per annum respectively, with board and laundry.

Birmingham General Dispensary.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, attendance, &c.

1913	325,420	2,899	328,319
1914	357,570	2,807	360,377

It should be explained that the licence duty payable by makers or vendors of patent medicine is in Great Britain 5*s*. per annum, and that the duty payable on medicine labels is 1½*d*., 3*d*., 6*d*., 1*s*., 2*s*., or 3*s*., according to the price of the medicine.

HEALTH AND SANITATION IN THE EAST AFRICA PROTECTORATE.

The report on the East Africa Protectorate for the year 1913-14 has been received at the Colonial Office and presented to both Houses of Parliament. In the section of the report dealing with medical matters it is mentioned that "if it were not for the disastrous effects of the epidemic diseases which so seriously affected the Protectorate during the year it could be said that a better standard of health was maintained than has yet been recorded. The grand total of those who presented themselves for treatment in 1913 was 108,520 as against 93,408 in 1912. The predominating diseases, affecting all zones in almost equal proportions, were diseases of the digestive, respiratory, and locomotory organs, and affections of the skin. Of the more preventable diseases malaria easily comes first, very few parts of the country escaping this infection. Dysentery also is generally prevalent. Antityphoid inoculation has been inaugurated." Then follow details, of which we subjoin a summary:—

Coast zone.—The number of cases of malaria treated was less than in the previous year, the decrease being to a great extent due to the spread of knowledge and an extended use of quinine. There were 11 cases of blackwater fever, and 1 case of trypanosomiasis, the subject being a derelict native brought in by the police, of whom no history could be obtained. There is a large field for research in the study of elephantiasis, as cases are common, though rarely presenting themselves for treatment. There were 208 cases of plague (as compared with 27 in the previous year), with a death-rate of 88·46 per cent., the vast majority of cases occurring in Mombasa. The type was largely bubonic, with a serious proportion of pneumonic cases. Small-pox occurred at infrequent intervals. The number of cases of dysentery increased considerably, the chief sufferers being imported labourers from Kikiyu and Kavirondo. There were 28 cases of beri-beri, the patients being all from up country. There were 4 cases of enteric fever (all Europeans), none of which proved fatal. There were sporadic cases of cerebro-spinal meningitis. The improvement in general conditions of health of the European population was satisfactorily maintained; malaria was the principal cause of sickness.

Mountainous area.—The health of both Europeans and natives was more satisfactory than in the previous year. There was an appreciable decrease in the number of cases of malaria; the type was largely subtertian. There were 3 cases of blackwater fever, 1 of which proved fatal. There were 25 cases of plague at Nairobi, with 19 deaths, and 31 cases at Kisumu, with a mortality of 87 per cent. 63 cases of small-pox were recorded, of which 12 were fatal. A severe outbreak of dysentery occurred amongst the labourers employed on the construction of the Eldoret-Londiani road. The total number of cases throughout the zone was 777, as against 612 in 1912. There were 21 cases of enteric fever, 1 of which proved fatal. The number of cases of cerebro-spinal meningitis reported was 288, with 152 deaths. The rains were early and prolonged, and it was during these cooler months that the epidemic was more apparent. Amongst the European population the most noticeable feature during the year was the large number of children's diseases, chiefly cases of intestinal trouble.

Kenya and Nyanza Provinces.—During the wetter and colder months rheumatic affections prevailed very largely in the neighbourhood of Mount Kenya. 3627 cases of malaria were recorded, as against 3134 in 1912. Some of the native chiefs in the Kenya Province have taken to sleeping under mosquito nets. One case of blackwater fever was reported. One imported case of sleeping sickness was discovered at Kisii, 30 or 40 miles from the lake shore, but notifications of the occurrence of this disease are yearly getting rarer. The epidemic of cerebro-spinal meningitis which broke out in May was the most disastrous experienced in the Kenya Province since the advent of European occupation. So severe was it that at one time it threatened to paralyse the interior economy of the province. It is quite impossible to estimate the number of cases, but it is probable that the normal sick-rate among the native population was more than doubled. The death-rate is estimated at from 3 to 10 per cent. above the normal. The infection did not reach the Nyanza Province till the latter part of the year. 31 cases of plague occurred at Kisumu, with a mortality of 87 per cent. There were 15 cases of enteric fever, with 3 deaths. For the first time on record no cases of small-pox were reported in the Nyanza Province, but desultory cases were met with in the Kenya Province.

Desert zone.—There were several cases of conjunctivitis and corneal ulcers, probably due to glare, sand, and flies. The predominating cause of sickness was malaria, 445 cases being notified in Kismayu alone. Dysentery was common in Jubaland, owing to the dependence of the population on the muddy waters of the Juba River and polluted wells. There were 2 cases of beri-beri and cerebro-spinal meningitis appeared in two instances. The general standard of health of Europeans in these regions has always been good, and this year was no exception; only 1 case of malaria was recorded.

Vaccination.—During the year 131,757 vaccinations were performed. The lymph used was prepared at the Government laboratory, and the quantity issued was 376,202 doses.

Sanitation and preventive measures.—The Sanitation Division of the Administration was created on April 1st, 1913, under a chief sanitation officer. In June Professor W. J. Simpson, C.M.G., professor of hygiene at King's College, London, arrived to inquire into the sanitary conditions of the Protectorate. Energetic measures are being carried out against mosquitoes by gangs maintained at Mombasa, Nairobi, and Kisumu. The measures adopted to suppress the outbreak of plague at Mombasa were house-to-house visitation, fumigation, segregation, inspection of travellers, and inoculation with Haffkine's prophylactic in 48,478 instances. Similar steps were taken in other parts of the Protectorate. No water-borne sewage scheme has yet been installed, but in a few isolated cases septic tanks have been added to residences. The single-bucket system is in vogue generally. The contents of the buckets are thrown into the sea at Mombasa, and buried in trenches at Nairobi, Kisumu, and other towns. Except in Nairobi, where the Bransby-Williams scheme is now well in hand, no township possesses a drainage scheme of a kind that can be regarded as satisfactory. At Mombasa and in the scattered residential districts the need is not acute owing to the absorbent nature of the soil, but in the more densely populated areas the question is of more importance. A large amount of the work performed by antimosquito gangs is caused by the absence of adequate provision for the removal of waste water. It must now be accepted that all African rivers are more or less polluted, and general filtration, &c., is most necessary before water can be considered fit to drink. The Mombasa service will not be completed for some time. Similar services are being taken in hand for Nakuru and Kisumu. Considerable work has been done during the year in bush cutting and in digging out roots. The alterations in the general appearance of certain areas in Mombasa, Nairobi, and Kisumu are very much for the better. The southern part of Mombasa is now clear of bush.

RHUBARB POISONING.

To the Editor of THE LANCET.

SIR,—In your issues of May 8th and 22nd I note letters from "M.D." and "M. L. J." relating illnesses apparently due to eating rhubarb. I should like to say that about two months ago I had a similar experience after partaking of rhubarb for lunch. Two or three hours afterwards I was seized with colicky pains in the abdomen, which gradually increased in intensity, and were shortly afterwards succeeded by rise of temperature, quick pulse, vomiting, and purging. I felt violently ill for a few hours; then the symptoms gradually subsided, and, unlike your correspondents, were not succeeded by any renal or vesical trouble. I should add that a lady of my acquaintance was made similarly ill just previously after partaking of stewed rhubarb at a meal. The symptoms may be attributed to the poisonous effects of the oxalic acid in rhubarb.

I am, Sir, yours faithfully,
May 25th, 1915. M.B.

THE DANCES OF GREAT BRITAIN AND HER ALLIES.

A RECITAL of patriotic dances will take place at 5.30 P.M. on Thursday next, June 3rd, the birthday of His Majesty King George V., at the Fyvie Hall of the Regent-street Polytechnic, Regent-street, London, W. The children taking part will be relatives of airmen, soldiers, or sailors, and the proceeds of the recitals will be devoted to the expenses of the wards for nursing wounded soldiers at the Heritage Craft Schools, Chailey, Sussex (Princess Louise Military Wards). Those who attend the recital are invited to bring gifts for the troops with them, such as handkerchiefs, socks, shirts, tobacco, cigarettes, sweets, gramophone records, books, and magazines; sheets, single or in pairs, will also be most acceptable. Tickets, price 5*s*., children 2*s*. 6*d*., can be obtained from Mrs. C. W. Kimmins, The Old Heritage, Chailey, Sussex.

There will be another performance at 7 on the same day and at the same place in aid of the same object. For tickets, price 2*s*. and 1*s*. 6*d*., application should be made to Mrs. Matthews, Glenkindie, Drewstead-road, Streatham, S.W.; Miss Graham, 38, Mecklenburgh-square, W.C.; Miss Kingston, 71, Corringham-road, Golder's Green, N.W.; or Miss Simmons, 8, Worple-avenue, Wimbledon, S.W. A stamped addressed envelope should be enclosed.

PERMANENT DISCOLOURATION OF THE SKIN.

C. W. (Wolverton, Bucks) writes as follows: "A man aged 53 had an attack of gout during the severe weather in January and February this year. With the gout he also had an attack of eczema. The penis, scrotum, anus, and calves of the legs were attacked by the eczema. In a month both gout and eczema were cured. The skin of the penis and scrotum is now normal, but that of the nates and the calves of the legs is of a dirty-brown colour. The patient has consulted several medical men with regard to this colour, and they have no suggestion to make. It was thought that in time the skin would become normal. Could any of your readers suggest a remedy to clear the skin on these parts? If the patient goes to the sea or the baths it is very inconvenient to have such patches of dirty skin visible! Is there *no* remedy?"

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.
THURSDAY.—Papers:—Mr. E. J. Russell: Soil Protozoa and Soil Bacteria (communicated by Mr. H. T. Brown).—Mr. C. Dobell and Mr. A. P. Jameson: The Chromosome Cycle in Coccidia and Gregarines (communicated by Prof. J. B. Farmer).—Prof. O. W. Richardson: The Influence of Gases on the Emission of Electrons and Ions from Hot Metals.—Prof. C. H. Lees: On the Shapes of the Equipotential Surfaces in the Air near Long Buildings or Walls, and on their Effect on the Measurement of Atmospheric Potential Gradiants.—Mr. J. W. Nicholson: The Band Spectrum associated with Helium (communicated by Prof. A. Fowler).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY.
SECTION OF ODONTOLOGY (Hon. Secretaries—F. Coleman, F. R. Smyth): at 8 P.M.
Annual General Meeting.—Election of Officers and Council for Session 1915–1916.
Casual Communication:
Mr. J. G. Turner: A Note on Extraction.
Paper:
Mr. F. J. Bennett: Recent Studies in Calcification of the Teeth.
THURSDAY.
SECTION OF DERMATOLOGY (Hon. Secretaries—S. E. Dore, A. M. H. Gray): at 5 P.M.
Adjourned Meeting.
Debate on the Pemphigoid Eruptions.
FRIDAY.
SECTION OF EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 P.M.
Paper:
Mr. Major Greenwood, jun., and Mr. G. Udny Yule: Anti-typhoid and Anti-cholera Inoculation: a Statistical Study.
WEDNESDAY (June 9th).
SECTION OF OPHTHALMOLOGY (Hon. Secretaries—Leslie Paton, Elmore W. Brewerton).
Cases (at 8 P.M.)
Paper (at 8.30 P.M.):
Mr. Fisher: Retinitis in Pregnancy.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.
THURSDAY.—4.15 P.M., Election of Officers, 1915–1916. Clinical Meeting.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, Society's Rooms, West London Hospital, Hammersmith-road, W.
FRIDAY.—8 P.M., Cases. 8.30 P.M., Paper:—Dr. F. S. Palmer: The Functional Palsies and their Recognition.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.
MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.
TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.
THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.
FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.
SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.
MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).
TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out patients (Dr. A. G. Auld); Surgical Out patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. H. D. Gillies). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting). 4.30 P.M., Clinical Demonstration:—Mr. J. Howell Evans: Selected Surgical Cases.
WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. Gillies). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients. 5.30 P.M., Eye Operations (Mr. R. P. Brooks).
THURSDAY.—2 30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).
FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.
MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M. Clinical Lecture.

KING'S COLLEGE (UNIVERSITY OF LONDON), Physiological Laboratory, King's College, Strand, W.C.
Course of Advanced Lectures in Physiology:—
MONDAY AND WEDNESDAY.—4.30 P.M., Prof. T. G. Brodie: The Gases of the Blood. (Lectures I. and II.)

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.				TO THE COLONIES AND ABROAD.			
One Year	£1	1	0	One Year	£1	5	0
Six Months	0	12	6	Six Months	0	14	0
Three Months	0	6	6	Three Months	0	7	0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD, AND Co., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters &c., have been received from—

A.—Messrs. Allen and Hanburys. Lond.; A. C.; Dr. J. Mitford Atkinson, Lond.

B.—Lieutenant A. Barr, A.V.C., France; Mrs. Behnke, Lond.; Messrs. W. H. Bailey and Son, Lond.; Mr. D. Beatton, Scalloway; Messrs. Burroughs Wellcome and Co., Lond.; Dr. D. T. Special terms for Position Pages.

An original and novel feature of "THE LANCET General Advertiser" is [illegible] Special Index to Advertisements on pages 2 and 4, which not only affords [illegible] ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County & Westminster Bank, Covent Garden Branch") should be made payable to the Manager Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to advertisements or subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agents for the Advertisement Department in France—SOCIÉTÉ EUROPÉENE DE PUBLICITÉ, 10, Rue de la Victoire, Paris.

THE LANCET, JUNE 5, 1915.

ABSTRACT OF

An Address

ON

ARTERIO-SCLEROSIS.

Delivered before the Cardiff Medical Society

By W. LYNE BLIGHT, M.D. DURH., F.R.C.S. ENG.

AFTER a brief introduction on the history of our gradually evolving conception of arterio-sclerosis, Dr. Blight continued:—

INCIDENCE AND CAUSATION.

Arterio-sclerosis is a disease which, although mainly incidental to the middle period of life and becoming progressively and cumulatively worse as age advances, yet occurs in young people and even in infants. It is more common in men under 50 years of age than in women, but after the climacteric period is passed it is as frequent in women as in men, if not more so. There are four general causes of arterio-sclerosis: (1) The normal wear and tear of life; (2) the acute infections; (3) the intoxications; and (4) those combinations of circumstances which keep the blood pressure high.

The occupations most subject to the wear and tear of life are those of navvies, blacksmiths, porters, labourers, soldiers, and mountaineers, whose persistent use of muscles over prolonged periods to an extent sufficient to cause hypertrophy of the heart is a most potent factor in causing a heightened blood pressure. The evidence of internal strain as a factor in raising the blood pressure is shown by the presence of sclerosis of the pulmonary artery in cases of prolonged mitral stenosis. Of the acute infections causing the disease the most important is syphilis, the others being the exanthems, influenza, and tuberculosis. Syphilis is the chief cause of arterio-sclerosis in infants and young people. Of the intoxications, the chief exogenous poisons are alcohol, lead, and tobacco. The chief endogenous poisons are those of gout, diabetes, Bright's disease, and obesity.

In the prodromal stages of the disease a spasm of the arterioles is chiefly brought about by irritation of toxic products causing a contraction of the muscular coat, which becomes hypertrophied, producing an increased peripheral resistance, with a compensatory increased force of the heart's action, causing its hypertrophy and a rise in the arterial pressure, which is the most frequent result of the persistent use of muscles. The normal blood pressure in persons under 30 years of age is 125 mm. Hg, and from this age onwards the blood pressure increases, but a pressure above 150 mm. Hg, except in the aged, is abnormal. Other causes of increased arterial pressure are excesses in food and drink. Dr. F. A. Mahomed believed that this high pressure in the arteries precedes the development of renal disease before the albuminuric stage of scarlatinal nephritis, and that in the red granular contracted kidney the disease was primarily in the blood-vessels generally. The regular or frequent use of adrenalin and other agents which raise the blood pressure causes a necrosis of the muscular fibre and elastic tissue of the media.

In the early stage of tubal nephritis high arterial pressure can only be produced by contraction of the muscular walls of the arterioles; and even in certain chronic forms this must still play an important part, but the presence of endarteritis obliterans produces and maintains the permanent peripheral resistance which leads to the high arterial tension of renal cirrhosis, as a physiologically hypertrophied heart cannot raise arterial pressure unless it is supported by a resistance in the systemic arterioles.

The blood-vessels are always in a state of activity, and they live under three main conditions: (1) That use maintains and in a measure sustains structure; (2) that over-use leads to degeneration; and (3) that at about 60 years or 70 years of age the arteries are unable to endure any longer the wear and tear of life; and if there be a poor variety of muscular and elastic tissue and fibre, as sometimes occurs not only in individuals but in whole families, the incidence of the disease, other conditions being equal, occurs at a much earlier period of life.

SYMPTOMS.

Arterio-sclerosis disturbs function by lessening the amount of blood supplied to an organ unless the blood pressure rises concurrently with the narrowing of the lumen of the vessel. The result is a slow progressive atrophy with gradual loss of function in all the areas supplied by a sclerotic vessel; and when the artery becomes finally obliterated, especially if it occur suddenly, necrosis and gangrene of the part normally supplied by the sclerotic vessel occur; hence gangrene of the foot in the arterio-sclerosis of diabetes. An artery attacked by the sclerotic process becomes irritable and liable to spasm; there is a sudden loss of blood to the part, with pain, loss of arterial pulse, and loss of function. The pain, when occurring in advanced stages of the disease, for instance, in the calf muscles, is frequently of a very severe character, and is more liable to occur in those patients who are of a full habit of body and have a gouty diathesis, frequently occurring in the night, and only relieved by opium. These vascular crises are the cause of the transient mono- or hemi-plegias, aphasia, paraplegia, transient amaurosis, anginal attacks, and probably of lead colic and the crises of tabes.

The premonitory symptoms of arterio-sclerosis are frequently evident in a middle-aged patient who comes to us complaining of headache, drowsiness, morning fatigue, feeling more tired when he gets up than when he went to bed, ineptitude for work, coldness of the extremities, tinnitus, attacks of migraine or neuralgia, together with high-pressure pulse and accentuated second sound of the heart. On the other hand, a middle-aged man may have a feeling of good health and may be able to perform the ordinary duties of his life, complaining of no symptom and perhaps priding himself on his fitness, and in whom no organic lesion was suspected to exist. Yet he may die suddenly by rupture of a cerebral vessel, thrombosis of a coronary artery, rupture of a small aneurysm, or acute dilatation of the heart. Death is thus the only intimation of anything being wrong with his system, demonstrating the great powers of adaptation of the body.

Another type of case is that of a man, beyond the middle period of life, who has worked hard with his muscles, eaten much, and drunk hard; he has a persistent elevation of the arterial blood pressure and for some years has been feeling unwell, suffering from insomnia, cerebral confusion, despondency, and nervousness. The insomnia is so distressing that the patients often resort to taking morphia or

No. 4788.

other hypnotic. The palpable arteries are found thickened and tortuous; there is an increased vigour of the cardiac impulse, the apex beat is displaced slightly outwards, the first heart sound is faint, dull or prolonged, or reduplicated or replaced by a murmur, and the second sound is accentuated with a loud ringing sound of a metallic quality.

An early symptom of the general disease is a slight pallor. As the vascular degeneration progresses the nutrition of the body generally and certain organs in particular suffer, the clinical history varying in every case according to the organ which suffers most and suffers earliest, whether brain, heart, or kidney; bronchitis and emphysema may be the first symptoms indicative of the disease. There is a gradual atrophy of the parenchyma of the various organs and tissues of the body, so that the patient ages visibly within a few years, loses his intellectual keenness and bodily vigour, the skin becomes flabby and lax, and the hair turns prematurely grey, though neither this nor arcus senilis is pathognomonic of arterio-sclerosis; the urine shows traces of albumin and tube casts may be present. Defective metabolism is frequently indicated by dyspeptic flatulence and intestinal troubles of various kinds. Anæmia becomes manifest. A patient under 40 years of age, the subject of this disease, will have symptoms of neurasthenia, be of an irritable temper, emotional, and suffer from sleeplessness.

It is probable the toxic agents are many and various, and arise from defective nitrogenous metabolism, and probably, as Bouchard suggests, consist of leucomaines produced in the body and ptomaines absorbed from the alimentary canal and improperly dealt with by the liver. When the sclerosis affects the cerebral vessels an early symptom associated with high blood pressure is headache, usually frontal and continuous, occasionally paroxysmal and resembling migraine. Another symptom is vertigo, usually transient and not so severe as in Ménière's disease, which may be accompanied by tinnitus and may occur with epileptiform crises, or, as in Stokes-Adams disease, with epileptiform and syncopal attacks with a permanently slow pulse associated with high arterial pressure.

Another important manifestation is the occurrence of transitory disturbance of function of parts of the brain or cord, leading to mono- or hemi-plegia, amaurosis, aphasia, and paraplegia, and ending in complete recovery. These attacks may be frequent, sometimes occurring on one side of the body and sometimes on the other, but their transitory nature, frequent occurrence, and complete recovery distinguish these attacks, probably due to angiospasm of the cerebro-spinal arteries, from the more serious ones of hæmorrhage, thrombosis, and embolism. Associated with these symptoms are various neurasthenic conditions, such as absence of mind, temporary derangement of mind, irritable temper, confusion of thought, dulness of comprehension or perception, failure of memory and faulty judgment in simple matters; an inequality in the size of the pupils, and exaggerated reflexes may be present, leading to a progressive dementia in which the grandiose delusions are usually absent.

Cardio-vascular System.

In the cardio-vascular system the sclerosis affects the valves, the myocardium, and the coronary arteries. The lesions of the aortic and mitral valves are due to a sclerotic process in the segments identical with that which goes on in the vessels. Most cases of aortic insufficiency in men occur from this cause. In the myocardium in the early stage there is a pure hypertrophy of the left ventricle owing to increased peripheral resistance and of the right ventricle to a less and variable extent. In the diffuse form of the disease there is a gradual failure of the hypertrophied cardiac muscle, which is a common and serious event, leading to dilatation, orthopnœa, slight œdema of the feet and beneath the eyes, cough and perhaps blood-stained expectoration, and progressive asystole. According to Basch, dyspnœa is the only criterion of cardiac insufficiency due to sclerosis, latent or incipient. It is often a most distressing symptom and frequently occurs in the night. An important subjective feature is breathlessness, especially on going upstairs or ascending a slight hill.

The objective symptoms are manifested by the visible, tortuous, pulsating, and thickened arteries, especially noticeable in the emaciated, senile, or prematurely senile patient. In the corpulent the only objective symptom of arterial change may be a high-pressure pulse at the wrist, the artery being firm and incompressible. A sphygmographic pulse tracing shows a gradual upstroke, no percussion wave, and a gradual down stroke in which the dicrotic wave is hardly visible. The pulse should be taken when the patient is standing up and compared with that when the patient is sitting or lying down. In the latter case under normal conditions it should become slower, but if it maintains its standing-up rate the state of tension in the arteries is unnaturally high or if the pulse become more frequent in the lying-down position it shows the still more advanced and serious state of the sclerosis. It is necessary to distinguish between the hard sensation conveyed to the finger by a high-tension pulse simply, in which case the pulse is scarcely felt when empty, and that in which there is a sclerosis and calcification of its walls and in which the artery is as prominent when empty as when full. These two conditions may, however, coexist.

The nutrition of the heart substance becomes inadequate from the increased resistance to be overcome and the participation of the nutrient vessels of the heart in the degenerative process, so that whilst the heart has increased work to do the quality and quantity of the blood-supply become progressively more impaired and the myocardium undergoes fatty or fibroid degeneration, resulting in a dilatation of the ventricle with a mitral murmur appearing, and dropsy, due partly to cardiac failure, partly to the hydræmic condition of the blood, and partly to the altered condition of the vessel walls, gradually increases in extent, the patient ultimately dying from hypostatic pneumonia. Myocardial degeneration and weakness are frequent results of the narrowing of the orifices of the coronary arteries by sclerosis, which also causes anginal attacks in young syphilitic subjects, but these attacks are more frequent when the main branches are involved. Dr. Mott believes that angina pectoris occurs especially in cases of increased peripheral resistance, and is not due to a mere stenosis of the coronary arteries without this resistance. The coronary arteries may be involved in this disease out of all proportion to the other vessels, and sudden death may occur in middle-aged men who had never had any cardiac symptoms, but on post-mortem examination a gradual fibrosis or perhaps areas of anæmic necrosis with softening and occasional ruptures are found.

Renal Symptoms; Hæmorrhages.

Although renal symptoms supervene in a large number of cases, widespread arterio-sclerosis may occur without nephritis or recognisable cause. The disease may be associated with small contracted granular kidney or come on insidiously in gout or chronic lead poisoning. The true arterio-sclerotic kidney is a red beefy organ which is firm, hard, and dark in colour, not at first reduced in size, sometimes even enlarged. Very often there are large flat areas of atrophy of the cortex, or a large section may be involved in consequence of an obliteration of the arteries passing to the part. The urine may at first contain no albumin, or if present it is not large in amount. The specific gravity is normal or sometimes high. Later on the albumin becomes larger in amount, and sometimes with cardiac dilatation the urine becomes scanty, with a large amount of albumin and numerous tube casts due to an intercurrent nephritis.

Hæmorrhages into the retina and choroid, epistaxis, hæmoptysis, hæmatemesis (which may be fatal), hæmaturia, and hæmorrhages into the subcutaneous tissue may occur as the result partly of high arterial pressure and partly of arterio-sclerosis. It was pointed out by Dr. Mahomed that even when the patient is much blanched by loss of blood the pressure in the arteries is still excessive.

TREATMENT.

The prognosis depends upon the stage of the disease. In the early stage of high arterial pressure much may be done by hygienic measures to prevent and arrest the disease. The patient should avoid all conditions which interfere with the nutrition of the body and lead as peaceful a life as possible, unattended by any mental worry or physical strain. Although a protracted holiday is helpful, it is not advisable for the patient to give up work entirely, but rather to lessen it in amount, and this will depend on whether marked cardiac failure, mental changes, or pronounced local features are present, and the advice will be given accordingly. Warm baths or occasional Turkish baths with friction and massage are helpful. A most important point in the treatment at this stage is that the food should be lessened in quantity and meat food almost abolished, as this, with the general mode of life, is the best way of lowering blood pressure. Natural aperient waters, as those of Cheltenham, in a moderate amount are beneficial. Generally speaking, all alcoholic liquors should be prohibited. The most useful drugs are amyl nitrite, trinitrin, erythrol tetranitrite, and sodium nitrite.

When fibrosis and calcification have taken place the damage is irreparable, but still the symptoms may be relieved and the arterio-sclerosis prevented from increasing. A milk diet is the best, especially at night, and when the patient suffers from a bad headache, dyspnœa, and insomnia these symptoms will often then disappear. In addition to milk as a general diet the patient may have oysters, fish—excepting those of the crustacean order—most vegetables, bread, butter, and buttermilk, and plenty of fruit. Iodide of potassium given for a period of some months has been most frequently used, but authorities differ as to its beneficial effect.

PTOMAINE POISONING AT LEEDS.—An outbreak of ptomaine poisoning in the Woodhouse district of Leeds continues to cause some anxiety. There are 120 cases, the condition of six of whom is still critical, and one death has been reported. The outbreak was first reported on May 22nd.

RHEUMATIC FEVER AND RHEUMATOID ARTHRITIS:

THE GEOGRAPHICAL FACTOR.

BY J. T. CLARKE, M.R.C.S., L.R.C.P. LOND., D.P.H.

VARIOUS theories have been published in the attempt to expound the cause of rheumatoid arthritis, but that none of them have been satisfactory is shown by the large amount of correspondence following any paper on the subject. In this paper I shall bring forward what I believe to be an unrecognised fact, and shall endeavour to show how it bears on some of the more common theories. I shall try to demonstrate that the geographical distribution of rheumatic fever and rheumatoid arthritis is the same, and shall argue that local as apart from universal distribution points rather to a specific cause than to the truth of any of the other theories of causation.

I must mention at the outset that Hirsch's book, which is still quoted as an authority on the geographical distribution of disease, was published as far back as 1886, and that there is much reason for correcting some of his statements; and as under the heading of rheumatism he "disclaims the possibility of making any sharp distinction between the several morbid processes included under the term rheumatism," his remarks on the subject cannot be accepted as having much value. I must also say at once that I am not writing about any of those diseases often called rheumatism, which are really pains or swellings due to other diseases such as syphilis, gonorrhœa, septic absorptions, or injuries; nor of the various pains in muscles and fasciæ such as lumbago or pleurodynia, nor of the pains due to the various fevers, influenza, dengue, or malaria, and many other pains often called rheumatism. The word rheumatism is now omitted from the nomenclature of diseases.

By rheumatic fever I mean the ordinary typical rheumatic fever, which I need not describe, but which, I would mention, has a special predilection for synovial and serous membranes, and by rheumatoid arthritis I mean the disease defined by Osler as "a chronic disease of the joints, of doubtful etiology, characterised by changes in the cartilages and synovial membranes with periarticular formation of bone and great deformity," in fact, the disease he calls arthritis deformans. The fact to which I wish to draw attention is that there is no rheumatic fever and no rheumatoid arthritis in the Malay Peninsula, and I shall produce some figures which will show that it is extremely probable that neither of these diseases occurs in any part of the tropics. By tropics I mean not merely hot countries, but that part of the world which lies between the north and south latitudes of 23° 28′, and in what I say I am considering only land at or near the sea-level. I mention this because Osler writes that "the two countries with the highest admissions in the British Army per 1000 of strength, Egypt and Canada, oddly enough, have climates the most diverse." But neither of these is a tropical country. Egypt is a hot country, but not tropical.

The following figures[1] show the total in-patients and the number of cases of rheumatic fever and of

rheumatoid arthritis in the Federated Malay States returns for the year 1911.

My attention was first directed to this matter in the post-mortem room, as I was never able to find a heart with rheumatic lesions of the valves. For 18 years I searched for rheumatic hearts and have asked other medical men to find me one, but so far I have not come across a single instance. In a period of this duration a medical officer in Malaya would have about 50,000 in-patients pass through his hands. During my search for rheumatic fever and for rheumatic hearts I have been also on the look-out for chorea, as it is generally considered to be a disease due to the same cause as rheumatic fever, but have found none. I have heard of two cases diagnosed as chorea, but this is so small a number that there is the possibility of errors of diagnosis; and the disease is not certainly always of rheumatic origin, as cases have been reported which followed gonorrhœa and the puerperium.

Rheumatoid arthritis I have also failed to find, and this concurrent absence of both rheumatic fever and rheumatoid arthritis in the Malay Peninsula contrasts so markedly with their concurrent presence in the temperate climates that it has left the impression that there may be a causal connexion between the two diseases.

In addition to my experience in one part of the tropics which I first recorded in 1896,[2] I now refer to the opinion of others.

Major Buchanan, I.M.S., wrote:[3] "Up to the moment we have no reliable statement to justify the belief that rheumatic fever (acute rheumatism) has been met with within the tropics." Unfortunately in mentioning India he did not distinguish between India as a whole and tropical India, which is only about one-third of the peninsula. It is obvious that in the higher tropical latitudes cases may easily have come from the temperate zones, and so might vitiate figures collected in Bombay or Calcutta, which are only just inside the tropics.

Mr. James Cantlie wrote[4]: "Rheumatic fever I have never seen in any hospital in China, India, or Egypt, in either native or European. This may be a faulty observation on my part, but I only state what I observed whilst on tour in India, during which I visited hospitals in Madras, Mudura, Bombay, Quetta, Lahore, Delhi, and Calcutta. In Egypt I never met with a case of acute rheumatism, nor in Hong-Kong nor South China during a nine years' residence." Mr. Cantlie's Hong-Kong experience is of fairly long duration and was in the tropics. Dr. McClosky, of Kuala Lumpur,[5] gave a similar result as the outcome of eight years' experience. Those who stated that they have seen cases of rheumatic fever in India do not state whether they saw them in tropical or non-tropical India.

From the *Journal of Tropical Medicine* (1911 and 1912) and from the Straits Settlements Medical Report I have collected the following figures:—

	Total cases treated.	Rheumatic fever.	Rheumatoid arthritis.
Singapore General Hospital	22,134 ...	Nil. ...	Nil.
Penang ,, ,, ...	6,870 ...	,, ...	6
Province Wellesley Hospital...	2,696 ...	,, ...	Nil.
Labuan	307 ...	,, ...	,,
Seychelles (Victoria Hospital)	388 ...	,, ...	,,
Northern Nigeria	Not given	684 ...	,,
Ceylon	78,065 ...	12 ...	,,
Grenada	1,823 ...	Nil. ...	,,
Gambia (Victoria Hospital)	666 ...	,, ...	,,
Nyassaland	20,560 ...	2 ...	,,

Of these figures, the 684 cases of rheumatic fever of Northern Nigeria are an obvious error of transcribing, for there are no cases of rheumatism, a heading which comes next below rheumatic fever and which in all the reports contains large figures. Only 2 of these cases are recorded as having died, and under "valvular diseases of the heart" there are only 13 cases. The medical report for the year 1910 for Ashanti, Northern Territories, and Gold Coast Colony is somewhat similar. Out of 43,618 cases treated there were 614 cases recorded as rheumatic fever with 1 death. I think that 1 death in 614 cases must throw some doubt on the diagnosis, but these figures may have got misplaced and should probably be placed under the heading rheumatism. In all these places many of the cases were probably diagnosed by native dressers; and native dressers when in a difficulty for a diagnosis are very apt to be satisfied with a name.

In most of these returns there are a few cases given of valvular disease of the heart. Some of these cases are probably the murmurs of dilated hearts, but post-mortem examination fails to find on the valves the vegetations of rheumatic origin. There are a certain number of atheromatous valves, but never have I found the rheumatic heart; and I do not think the atheromatous valve can be confused with the vegetative lesion of rheumatic fever.

I have by me the 1912 medical report of the Straits Settlements, which is a very full report. In Singapore hospitals there were 22,134 cases treated with 2584 deaths, but the words rheumatic fever, rheumatoid arthritis, and chorea do not appear. Under the heading rheumatism there are 63 cases with 1 death. Were these cases true rheumatic fever or did they even include a few cases of rheumatic fever I think there would be more deaths. There were 52 cases of valvular disease of the heart, a number which is suggestive when compared with the number which are found in the hospitals of temperate climates. Atheromatous hearts would easily supply this number, and Singapore is one of the big ports of the world; 409,328 passengers and 130,349 crew were examined in Singapore harbour, and these coming from all over the world might provide a few cases of rheumatic heart if any were found. In the post-mortem room of the pathological department, Singapore, there were performed 1422 necropsies, among which were found 19 cases of aortic chronic endocarditis and 7 cases of mitral chronic endocarditis. If in a post-mortem room which serves a population of 312,000 inhabitants only 7 cases of chronic mitral endocarditis are found, if in a hospital return of 22,134 patients there are no cases given of rheumatic fever, chorea, or rheumatoid arthritis, I think I am justified in my statement that these diseases do not occur in Singapore.

In almost every number of the *Journal of Tropical Medicine* are published the annual returns of some tropical country, and all show the same absence of rheumatic fever and of rheumatoid arthritis. Occasionally a medical man is met with who asserts that he has seen a case of rheumatic fever in the tropics. I have heard of a case diagnosed as rheumatic fever which turned out to be syphilis, and I was shown a supposed case which was undoubtedly a septic joint occurring in a case of dysentery. For the majority of the tropical countries the figures in the returns under these headings are zero, and I contend that in view of the number of cases in which the figure is zero, in view of my own experience and that of the writers I have quoted, and in view also of the small numbers diagnosed as valvular disease of the heart, the probability that the few cases given are either an error in diagnosis or in the subsequent transcription of the returns is greater than the probability that they are true cases of these diseases. And I further contend that these facts are sufficient to throw doubt on the statement of anyone who claims to have seen one or two cases. In other words, I claim that these diseases do not occur in the tropics.

[2] Indian Medical Gazette, December, 1896.

[3] Journal of Tropical Medicine, December, 1899.

[4] Ibid., October, 1899.

[5] Ibid, January, 1900.

In contrast with the figures I have given those of Dr. Karl Grassmann[6] are worth attention. He gives the deaths due to the circulatory apparatus at ages 15 to 30 as 7 per cent., and at the ages 30 to 60 years as 14·15 per cent. of all deaths for Germany. This, when compared with the 0·0 per cent. of most tropical countries, or even with 0·26 per cent. of Singapore, is very remarkable.

Without necessarily accepting Poynton and Paine's bacillus as the cause, there are many reasons for considering that rheumatic fever is a specific disease dependent on one particular organism. According to Newsholme rheumatic fever shows great irregularities in its incidence from year to year. Seasons of epidemic prevalence tend to extend over periods of one to three years, with intervals of three, four, or six years. Epidemics vary in intensity. The death-rates are similar to those of some specific diseases; there are seasonal variations. It is more common in the towns than in the country; its greatest incidence is on the young. And I submit that its absence from the tropics is another link in the chain of evidence that it is a specific disease. There is another specific disease, scarlet fever, which does not occur in the tropics, but I know of no non-specific disease which does not occur in the tropics.

There are various theories of the etiology of rheumatoid arthritis:—1. That it is a neurosis. 2. That there is a deficiency of lime salts. 3. That it is due to a disturbance of metabolism. 4. That it is caused by absorption from chronic sores such as those of pyorrhœa alveolaris, or those in the region of the anus. 5. That it is due to insufficient sweating. 6. That it has a relationship to rheumatic fever. 7. That it is a specific disease. Of these the first four are just as likely to occur in the tropics as in the temperate climates, and the fifth is just as likely to be an effect as a cause and is very variable in different people in the tropics. No. 6 of these theories is supported by the geographical distribution. Neither rheumatoid arthritis nor rheumatic fever occurs in the tropics, and both are common in certain parts of the temperate zones.

The chronic absorption theory is very attractive, but absorption from chronic sores usually results in anæmia of a kind which is in no way characteristic of rheumatoid arthritis; and when a joint is enlarged as a sequel to a chronic sore, as in dysentery, an organism is found in the joint, which in no respect resembles the joints of rheumatoid arthritis. Where an inflamed joint is the result of a chronic infection the incidence is often on one joint only which may suppurate.

It is begging the question to label rheumatoid arthritis as fibrositis and to give it and all fibrosites the same etiology. The theory that rheumatoid arthritis is a specific disease is the one which seems the most probable. The symptoms are very definite, especially in the acute cases. Those of one case are as much like those of another as are the symptoms of any of the specific diseases. Two typical cases are almost facsimiles of one another, and the sometimes sudden onset bears in the same direction. But the point on which I rest my claim that it is a specific disease is its geographical distribution. It occurs in one part of the world and not in another; and the most likely reason for this is that the heat of the tropics is inimical to some organisms.

Many parasites are peculiar to hot climates, but many animals and plants can live only in the temperate zones, and just as some organisms are thermophilic so others have a low optimum temperature. I would here refer to the bacillus mycoides, which normally will not grow above 22° C., but which by gradually increasing the temperature can with difficulty be made to grow at a temperature of 37° C. It then, after a few passages through guinea-pigs, loses its flagella, develops a capsule, and produces symptoms in all respects similar to those of anthrax.[7] In the same way the natural optimum temperature of the organism of rheumatoid arthritis may be low and yet it may, with difficulty at first, be capable of living at the body heat; and I go so far as to suggest that it might be best cultivated at very low temperatures.

In this paper I have endeavoured to add to the reasons for believing that rheumatoid arthritis is a specific disease, that it may have a relationship to rheumatic fever or possibly require that disease as an antecedent; and I believe that the knowledge that these two diseases are absent from the tropics may give a clue to their etiology, but especially to the etiology of rheumatoid arthritis. Finally, I must mention that Dr. Leigh Canney[8] writes of Egypt as providing an almost certain cure for rheumatoid arthritis. Egypt is not in the tropics, but in some parts its climate is somewhat similar to that of the tropics, and I suggest that many cases of rheumatoid arthritis would be benefited by a stay in the tropics.

Since writing the above there has appeared in the *Indian Medical Gazette* of January, 1915, the Review of a Year's Medico-legal Work in the Calcutta Morgue (1913). 281 cases were examined. Under the heading of disease of heart and blood-vessels the following figures are given:—

	Endocarditis and endarteritis.	Atheroma.
Aortic valve...	Nil.	44
Mitral valve	,,	0
Thoracic aorta	,,	45
Pulmonary artery	,,	1
Coronary artery ...	,,	1

	Aortic valve.	Mitral valve.	Thoracic aorta, first part.
Stenosis ...	Nil.	Nil.	Nil.

TUBERCULOSIS SCHEME FOR PLYMOUTH.—The sanitary committee of the Plymouth borough council has recommended a tuberculosis scheme for the town, to include the erection of pavilions at Mount Gold Hospital, providing accommodation for 52 patients, and the acquisition of 42 beds at various sanatorium institutions and 4 beds at general hospitals for cases necessitating surgical treatment. The cost of the undertaking will involve an annual expenditure of £8496.

A CASE OF LANDRY'S PARALYSIS.

By J. S. B. STOPFORD, M.B., CH.B. MANCH.,
LECTURER IN ANATOMY, UNIVERSITY OF MANCHESTER.

THE following case was admitted to the Rochdale Infirmary in August, 1912, under the care of Dr. D. Richmond, honorary medical officer to the hospital, to whom I desire to express my thanks for permission to investigate the pathology of the case and publish the notes.

The subject of this report was a robust, athletic young man, 18 years of age, who had gained considerable repute as a weight-lifter and swimmer, and who had never suffered from any illness since childhood. He was a teetotaler and had never contracted any venereal disease. He had complained of transient attacks of severe pain in the lumbo-sacral region for some seven weeks previous to the onset of the paralysis, which he attributed to stooping at his work in the mill. Some weeks before the onset he had been in camps in the Isle of Man and had there been repeatedly wet through.

History of present illness.—The patient noticed whilst out walking with some friends on Sunday afternoon, August 26th, 1912, that his left leg began to give way. It grew rapidly worse, and he had considerable difficulty in reaching home owing to increasing weakness of both legs. After having tea he attempted to go out again, but only succeeded in getting about 200 yards away when he had to give up. He was assisted home and put to bed. He had a good night and slept well, but awoke to find he was quite unable to move either leg. On pushing them over the side of the bed and attempting to stand up he fell to the ground and had to be lifted into bed. Later in the day he was seen by his doctor, who advised removal to hospital, where he was admitted at 5.30 P.M. (August 27th).

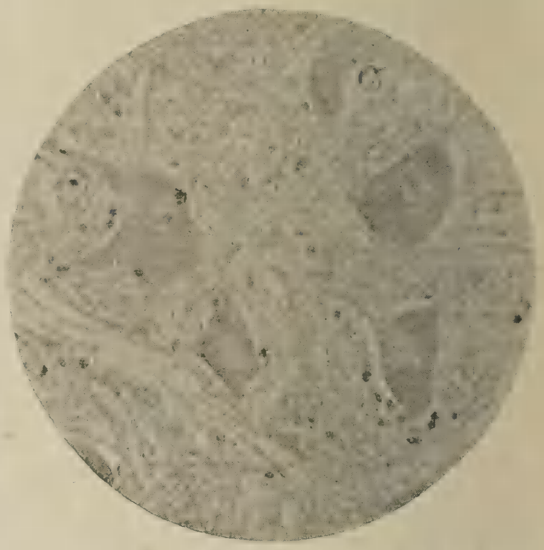
Condition on admission (24 hours after onset).—Besides the paralysis he complained of a tingling sensation in both feet and abdominal pain, somewhat of a "girdle" type, in the region of the lower costal margin. His appearance was that of a healthy muscular young man and his mind was quite clear. Temperature 99° F.; pulse 76 per minute, regular, strong, and good tension. (*a*) *Muscular system.*—Complete flaccid paraplegia—no voluntary movement even at the hip-joint, and apparently no muscle of either leg spared. Slight weakness of the hand-grasp, but no weakness at the shoulder. Practically no abdominal respiratory movements. No tenderness or wasting of the affected muscles. (*b*) *Sensation.*—Tactile sensation (tested by a wisp of cotton-wool) normal except for slight impairment on the soles of the feet. Sensation of pain, heat, and cold normal. (*c*) *Reflexes.*—Superficial and deep reflexes absent except the cremasteric, which gave slight response (abdominal reflexes absent). Organic reflexes normal. No deformity of spine or tenderness at any point. Special senses and cranial nerves normal. Respiratory and cardiovascular systems and urine normal, although respiration was somewhat feeble. The spleen was not palpable.

Progress of the disease.—August 28th: The hand-grasp on both sides rapidly became weaker. Retention of urine throughout the day, necessitating the use of a catheter at night. (This was thought to be due to the weakness of the abdominal muscles.) August 29th: The difficulty in breathing caused discomfort, and the dyspnœa became more pronounced during the day. He was now unable to move the fingers, and both arms were much weaker. The movements at shoulder- and elbow-joints had become very limited, especially the latter. He passed urine freely without any difficulty. August 30th: Respiration became much embarrassed and purely diaphragmatic in type. There was almost complete paralysis of both arms. No retention of urine. August 31st: The arms had now become flaccid and totally paralysed. Respiration was even more laboured, causing some cyanosis. Dysphagia and slight difficulty in protruding the tongue were experienced during the day. Some paresis of neck muscles seen for the first time, but eye muscles unaffected. At night he complained of "feeling funny in the head," and of "saying things he did not intend to." Sept. 1st: During the early hours of the morning the dyspnœa became steadily worse and he died of asphyxia at 6 A.M.—i.e., 5½ days after onset.

Necropsy.—Unfortunately permission was only granted to examine the spinal cord. This, however, was removed with as much of the spinal nerves as possible. The spinal cord was of firm consistency throughout, and exhibited no macroscopic change except well-marked general vascular engorgement. After hardening, portions were removed from the cervical, mid-dorsal, and lumbar regions, and also pieces of the nerve roots and cauda equina for histological examination.

Histological examination.—After cutting sections of the various regions of the spinal cord and nerves they were stained by the following methods: Nissl's toluidin blue, Marchi, Weigert, Van Gieson, and Bielschowsky.

Spinal cord.—At first sight the changes were not at all obvious, being confined to the motor cells. The majority of these were seen to be swollen and rounded rather than angular, retaining fewer processes, and they stained badly by Nissl's method. (See figure.) There was almost complete absence of any chromatin granules, the protoplasm appearing homogeneous except in a few instances where some granules remained at the periphery of the cell. In many of the cells no nucleus was to be found, in others the nucleus was ill-defined owing to its inability to retain the stain and was placed excentrically, whilst in a very few the nucleus was only slightly displaced from the centre of the cell, but was swollen and badly stained although its excentric nucleolus was generally deeply stained. These changes were seen in the multipolar cells of the anterior and posterior cornua and Clarke's column, and the changes appeared to be quite as well marked in the cervical as in the lumbar region. There was no proliferation of the neuroglial cells. The vessels in both the grey and white matter were distended with blood, but no hæmorrhages or perivascular infiltration were seen. There was no cellular infiltration of grey matter or meninges as seen in poliomyelitis. Marchi's stain failed to demonstrate any degeneration in the nerve fibres of the cord.



Section from a case of Landry's paralysis showing cells of anterior cornu.

Nerve roots and nerves of cauda equina.—No pathological change could be found in any of the numerous longitudinal and transverse sections of the nerve roots and nerves of the cauda equina which were examined. Staining by the usual methods for demonstrating the presence of micro-organisms failed to reveal any.

Remarks.—Until the pathology of Landry's paralysis is definitely established and universally accepted it appears to be one's duty to make, as far as possible, a full histological examination of the nervous system in all cases of acute ascending paralysis.

Since Landry's[1] paper was written in 1859 improved methods of staining nervous tissues have shown that cases of poliomyelitis and peripheral neuritis can produce a clinical picture practically identical with his case; and we shall never know whether his case was not one of these conditions. Ross and Judson Bury[2] were probably the first to suggest that Landry's paralysis was possibly a type of peripheral neuritis, and since the publication of their treatise many have recorded cases of acute ascending paralysis in which the pathological changes were those of a polyneuritis. Recently Pfeiffer[3] has published a full clinical and pathological report of such a case, and states that "it seems most probable that the pathology of this condition (Landry's paralysis) *per se* is to be looked for in the peripheral nervous system." Many writers have shown that acute poliomyelitis may show symptoms of an "ascending paralysis," and Harbitz and Scheel[4] have stated that many cases published as Landry's paralysis are really severe forms of poliomyelitis.

Nevertheless Buzzard[5] and Williamson[6] maintain that there is a distinct morbid condition worthy of the name Landry's paralysis. Buzzard[5] describes three cases, and in each a histological examination of the nervous system revealed an identical morbid change. The morbid change, and this only a slight one, was confined to the multipolar nerve cells of Clarke's column and the anterior and posterior cornua; there being a pericentral chromatolysis and in some cases excentration of the nucleus. No cellular infiltration of the vessels or white matter occurred, and no change was found in the peripheral nerves except the fine droplets of fat seen after staining by Marchi's method. This latter appearance Buzzard considers of slight importance, since he has seen it in all sorts of toxic conditions irrespective of paralysis.

The condition found in my own case showed an almost identical state of affairs. Although I should have preferred to examine the peripheral nerves more completely, it is probable that some indication of neuritis would have been found by the examination of the nerve roots and cauda equina, if it existed. Similar pathological changes have been reported in cases of acute ascending paralysis by Sheppard and Walker Hall,[7] Courmont and Bonne,[8] and others.

There is still considerable controversy about the pathology of Landry's paralysis, and on reading many of the published cases one is impressed with the chaotic state of the literature concerning this subject. This appears to be due mainly to two factors: in the first place Landry was unable with the methods of staining at his disposal to find any morbid changes, and secondly, the unfortunate alternative name, "acute ascending paralysis," seems to be responsible for the publication of many cases of poliomyelitis and polyneuritis as instances of Landry's paralysis. As we can never ascertain with certainty the actual disease from which Landry's own cases suffered, it would appear more satisfactory only to classify those cases of acute ascending paralysis as Landry's paralysis which do not show histological changes which can be identified as those of poliomyelitis, polyneuritis, &c. If the cases left after such a process of elimination were submitted to a full examination it seems probable that the present confusion would in a short time be remedied, and the pathology of the condition universally accepted. No useful purpose can be served by classing all cases of acute ascending paralysis as Landry's paralysis regardless of the pathological changes, and the sooner the alternative name for Landry's paralysis becomes obsolete the earlier will the point of controversy be decided.

I do not intend to discuss the clinical diagnosis of this disease, as this most difficult task has been considered very fully by other writers.

Summary.—1. We shall never know the precise pathological changes in Landry's cases. 2. Several nervous diseases can produce an acute ascending paralysis. 3. There is good reason to suppose that there is a distinct morbid condition causing a train of symptoms similar to those described by Landry and worthy of the name "Landry's paralysis." 4. There is no advantage in retaining the alternative name "acute ascending paralysis," and the name "Landry's paralysis" should be strictly reserved for a special type of ascending paralysis which does not show the morbid changes of poliomyelitis, polyneuritis, &c.

Manchester.

ON THE GENESIS OF CONSTITUTIONAL GASTROPTOSIS.

BY JOHN J. GRACE, F.R.C.S. ENG.,
CHIEF ASSISTANT IN THE X RAY DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL;
AND
WALKER OVEREND, M.A., M.D. OXON.,
CHIEF ASSISTANT IN THE X RAY DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL; LATE PHYSICIAN TO THE PRINCE OF WALES'S HOSPITAL, LONDON, N.

Introduction.

As a preliminary to the discussion of this question we give a brief description of two out of several cases which have come under our observation.

CASE 1.—A female, aged 43 years; tall, thin, complexion rather pale, hair quite white; childhood healthy; in fact, clinical history negative until five or six years ago, when she began to complain of backache. This occurred after a long spell of strenuous nursing with much lifting of patients. A palpable right kidney was found. Increasing uneasiness and discomfort after meals induced her medical attendant to suggest a bismuth meal. There had been no sickness. The measurements of the chest and abdomen were: (1) Minimum circumference of the abdomen between inspiration and respiration, 26 inches; (2) distance from the level of the upper edge of the clavicles and symphysis pubis, 21 inches; (3) distance from the sixth dorsal spine to the level of the iliac crest, 8 inches; and (4) circumference at the level of the nipple (mean), 28·75 inches.

$$\text{First enteroptotic index } \frac{21 \times 100}{26} = 80$$

$$\text{Second} \quad ,, \quad ,, \quad \frac{26}{8} = 3{\cdot}25$$

$$\text{Relations of girth} \quad \frac{28{\cdot}75}{26} = 1{\cdot}1$$

Two ounces of bismuth subcarbonate well mixed with 10 ounces of bread and milk were administered, and a radiogram, with the patient lying on the couch, was taken after 20 minutes. In the diagram the depth of the lesser curvature, even in the recumbent position, lies at the level of the umbilicus and iliac crest, whilst the lower edge of the greater curvature closely approximates the pelvic brim. On the screen, the antrum was small but active; the sinus or vestibule lay in the ascending loop. The pylorus and cap were low, and the whole stomach resembled a tube of uniform calibre. Later it was seen that the transverse colon skirted the pelvic brim, the hepatic and splenic flexures were little if at all displaced, and the liver dulness was normal. The muscles of the abdominal wall exhibited apparently no relaxation of tone.

CASE 1.—Patient in the recumbent position. D, Diaphragm. F, Fornix. GC, Greater curvature. LC, Lesser curvature. C, Cap of duodenum. VC, Vertebral column. ICr, Crest of ilium. A dark circle indicates the umbilicus.

CASE 2.—The patient, a female, aged 68 years, had suffered from indigestion for two or three years, previous to which she had not experienced any bad health. But about that time her husband became bedridden and required constant attention both day and night for nearly two years. She began to suffer from sickness two months ago; she had never had hæmatemesis. There were much wasting and occult blood in the stools. A test-meal showed the presence of hyperchlorhydria. There was pain in the lower part of the chest passing through to the back one hour after food, which was relieved by vomiting. Liver dulness was normal. There were epigastric tenderness, a palpable right kidney, and constipation. First enteroptotic index = 87; second enteroptotic index = 2·7 (*vide infra*).

In the recumbent position the stomach was cylindrical except in the lower portion, where it was somewhat dilated (secondary atony); the lesser curvature was at the level of the umbilicus, the greater curvature about 3 inches lower. After 24 hours the cæcum and colon were still uniformly filled with the opaque meal; the hepatic flexure was at the level of the crest of the ilium, the transverse colon over 2 inches below the umbilicus, the splenic flexure normal, and the iliac and pelvic colon dilated. For the notes of this case we are indebted to Dr. H. Morley Fletcher.

The Theories of Origin.

In total gastroptosis the stomach, possessing an even diameter, presents the appearance of a long U-shaped tube with the antrum and cap situated at the extremity of the ascending limb. It has no resemblance to the contour of the normal stomach, and has apparently reverted to a primitive type. The fornix is diminutive, the corpus elongated and slender. Its production has been ascribed to the effect of a vertical distension exercised by weight and gravity upon a relaxed and yielding muscular wall. To explain the deviation, sometimes trivial, from the normal time of gastric evacuation, it has been assumed that while peristalsis is normal or actually increased the tone or peristole alone is impaired. The idea is invalidated by the fact that uncomplicated examples exhibit no sign of the transverse dilatation which ensues when a normal stomach becomes atonic. We must therefore reject the opinions of authorities who refer its causation to a weakness of the muscular layers. No doubt atony may follow as the final result of hyperacidity and ulceration, but this loss of tone is secondary.

Since its presence is often associated with a diminished lower thoracic and upper abdominal capacity, it has been maintained that, at the age of puberty, when every organ is striving to assume the size and configuration of the adult form the lessened space existing between neighbouring viscera—liver, kidneys, spleen—by concentric pressure hinders the stomach from expanding in the horizontal direction. As a result it grows in length whilst preserving its volume unchanged. This idea, although attractive, does not survive careful examination.

The diminished upper abdominal cavity is generally due to the peculiarities of the paralytic or expiratory thorax. In the absence of early disease, which may materially modify the normal outlines of the lower thorax, this unusual form must be attributed to a *congenital* or *hereditary* origin. The chest is long and flat; the lowest costal arches closely approach the iliac crest. The line of the ribs forms an acute angle with the sternum, and there may be a floating tenth rib. Below the intermammary region there is, in reality, a general downward displacement of both soft and osseous tissues of the thorax—an altered direction of growth.

An attempt has been made to find a numerical expression for this change. The distance from the level of the upper margin of the clavicle to the symphysis pubis is divided by the minimal circumference of the abdomen and the fraction obtained is multiplied by 100. In women the figure is usually about 75, in men about 66. An index above 80 is often found in palpable right kidney and in the asthenic constitution. A more reliable index may perhaps be obtained by substituting for the denominator the distance between the level of the sixth dorsal spine and that of the crest of the ilium, and placing the minimal circumference of the abdomen as numerator. A normal figure gives 3, in the habitus asthenicus it may fall below 2. The upper part of the chest and the upper lobes of the lung are not really concerned. Also the relation of the intermammary circumference to the minimum abdominal is of interest.

Nevertheless, these figures, although instructive, are not of primary value. There are individuals with extreme indices who do not exhibit the slightest sign of enteroptosis. On the contrary, they may exhibit gastric hypertonus, with high hepatic and splenic flexures, non-palpable kidney, and normal liver dulness. Such a patient gave these numbers:—

(*a*) Clavicle to pubic symphysis...	22·5 inches.
(*b*) Minimal (mean) abdominal circumference	23·5 ,,
(*c*) Spine of the sixth dorsal to the level of the iliac crest	11 ,,

$$\text{First index (thoracico-abdominal)}\ \frac{22{\cdot}5 \times 100}{23{\cdot}5} = 95$$

$$\text{Second index (mid-thoracico-abdominal)}\ \frac{23{\cdot}5}{11} = 2{\cdot}1$$

Also many cases of gastric ulceration, chronic appendicitis, and habitual constipation possess abnormal indices and do not show a trace of gastroptosis. We have not yet seen the converse—that is, pure general gastroptosis with normal or supranormal indices; its occurrence, however, is indubitable.

The investigations of Professor A. Keith[1] and Professor C. S. Sherrington[2] have shown that the support of the abdominal organs is largely a question of the integrity of reflex arcs and abdominal muscles, the length of visceral bands and mesenteries playing a part of secondary importance only. In the dead subject, when erect, removal of the abdominal muscles induces a degree of ptosis far beyond any displacement observed during life. The tonic contraction of these muscles—recti, obliqui, and transversi—which occurs on standing, is evoked by a reflex the afferent end organs of which lie in the profuse terminations of the peritoneal nerves, including the Pacinian bodies. A failure or weakness of this reflex has been assigned as a cause of Glénard's disease. Keith has also drawn attention to the occurrence of a quasi-inflammatory process in the peritoneum between the third and fifth months of intra-uterine life. This seems to be a necessary expedient for the attainment of the upright position.[3] The result is fixation of the mesenteries to the spine, the ascending colon to the kidney, the back of the cæcum to the abdominal wall, and the terminal ileum to the iliac fossa. One of the objects in view is the prevention of twists and obstructions of the canal.

In the constitutional gastroptosis now under consideration the abdominal muscles are often firm and tense in comparison with their condition in secondary splanchno-ptosis. We cannot, therefore, attribute the descent of the gastric viscus to an acquired laxity of the abdominal wall. The genesis is to be ascribed to the existence of prolonged attachments due to a deficient development of the embryonal adhesive processes already mentioned. This defect will be reinforced by the presence of a narrow upper abdominal opening, by downward displacement of the diaphragm, and by certain osseous changes which take place at the age of puberty. It is, in fact, a partial indication of a general innate or embryonal anomaly, in which an aberrant configuration of the chest, elongated ligamentous bands of the abdominal viscera, prolapse of the stomach, liver, kidneys, terminal ileum, cæcum and colic flexures may one or all participate. Naturally the picture is often incomplete, not only as regards the number of the factors involved, but also in the degree. The relations of the neuromuscular and nodal tissue[4] (myenteric plexus) and of imperfections in the maternal internal secretions to this hereditary error present interesting problems for the clinician and pathologist.

Individuals of this habit, more especially men, often exhibit little or no digestive disturbances. There may be some gastric delay, with a tendency to diffuse habitual constipation associated with a liability, above the average, to impairment of health under conditions of strain. The two cases described in the introduction illustrate the dangers of continuous abdominal stress. This may lead to relaxation of these muscles, increased prolapse, and to gastric difficulties followed by hyperacidity, ulceration, and chronic gastritis. The acquired inter-adjustment of years is dissolved.

As long as reasonable care is taken in the way of food, exercise, and mental activity no evil effects may arise, and life may be prolonged even beyond the normal span. A prudent protected mode of living is generally instinctively chosen. In the case of the individual, however, with feeble and unstable nervous organisation, gastric neurasthenia, intestinal stasis, and toxæmia with colitis may supervene and become severe and chronic.

Several secondary causes, contributory to the full evolution of the type, may arise during childhood; these are tuberculosis, thymo-lymphatism with incoördination of the internal secretions, and grave attacks of the infectious fevers. Tuberculosis of the lung, even if old and obsolete, may have increased the erratic development of the chest by implication of the diaphragm; hypertrophy of the thymus may produce premature ossification of the costal cartilages; while the incidence of serious attacks of measles, diphtheria, pertussis, and scarlet fever may induce general relaxation of muscular tone, favour the development of tuberculosis, and may leave indelible marks on the future metabolic processes of the whole organism.

SOME POINTS IN THE CIRCULATORY SYSTEM IN ANKYLOSTOMIASIS:

A NEW EXPLANATION FOR THE MURMURS.

By ABD EL AZIZ ISMAIL, M.R.C.P. LOND.,
D.P.H. LOND., D.T.M. & H. CANTAB.

THE hook-worm is responsible for Egyptian chlorosis, which affects from 6 to 15 per cent. of the adult population of the country. Even in a crowded out-patient room variations in the reserve force of the heart are striking. Three stages seem to stand out. Further observations have convinced me that these are quite distinct, and that the majority of patients present one stage or the other.

Description of Typical Cases.

The following is a description of typical cases in the various stages.

Stage I.

Complaint on admission.—Breathlessness, dyspnœa, palpitation on exertion, throbbing of the veins of the neck, and epigastric pulsation.

Physical signs: arteries, heart, and chest.—The apex beat is distinct in the fifth space inside the nipple line, often quite an inch. There are pulsation in the second and third left intercostal spaces, epigastric pulsation, and arterial throbbing in the neck. The deep cardiac dulness is unaffected or slightly diminished. The chest is hyperresonant The circumference at the fourth interspace is 86–92 cm.; this is an average increase of 8 cm., the difference between full inspiration and expiration being almost one and a half times the normal. No less than 60 per cent. show a systolic murmur at all the orifices, loudest at the apex or base, specially the second to the third left costal cartilage. In this connexion the basal murmurs were more related to the degree of anæmia than the apical, and often in the progress of the case the apical heart sounds became clear while the pulmonary murmur persisted. The second sound at the pulmonary area was accentuated or doubled in four-fifths of the cases.

Whenever the anæmia is under 40 per cent. the *bruit de diable* is almost sure to be present by listening over the jugular bulb. It is the only murmur that has a distinct relation to the degree of anæmia. Pulsation of the jugular often exists, and the rise in the tissues covering the vein will be found to correspond with a distinct *a* wave in the jugular tracing, which is normal. The *v* wave is not abnormally marked. No ventricular type of curve was seen.

[2] Sherrington: The Integrative Action of the Nervous System.

Keith: Human Embryology and Morphology, third edition, p. 267.

[4] Keith: British Journal of Surgery, April, 1915, p. 648.

At rest the pulse is usually 80–100, with an average of 92 per minute, but some 5 per cent. show 60–72. The systolic blood pressure is 110–130, and the diastolic 70–100 mm. Hg.

State of other organs and the reserve force of the heart.—At this stage the patient is fairly nourished and with a yellow tinge in the conjunctiva. There is no dropsy, no enlarged liver, and the amount of urine, which may be of low specific gravity, is normal. On walking 100 metres the pulse-rate rises 5–12 per minute, and the respirations rise from an average of 22–24. Walking on level ground does not seem exhausting. I have known patients walk for miles with little rest before coming to the hospital out-patient room. The majority were able to attend to their agricultural duties, involving manual labour, till three to seven days before admission. One porter at a railway station was attending to his duties two days previously. On running, however, for 100 yards dyspnœa becomes evident and the respirations rise over 30, the pulse-rate being 110–120 per minute. If the exertion is continued there is a further rise in the pulse-rate up to 130, but the respirations with more exertion may be 60 per minute. The patient then feels giddy and breathless, and is forced to sit or lie down. Some suffer more from the throbbing of the arteries in the neck, which is then extreme, and also from palpitation. In none of this group could a history of cardiac pain or attacks of angina be obtained. Certainly none were observed in the hospital. Going upstairs is more exhausting than running.

Areas of hyperalgesia were looked for in the left mammary region, the left arm, left sterno-mastoid and trapezius, and in none were they present. Some 5 per cent. showed, however, slight tenderness on the ulnar side of the left forearm, of which the patient was unaware previously. No hallucinations or attacks of depression could be made out if pellagra, which so often complicates the disease, be excluded.

This description refers to the majority of cases of this group. But some will show absence of one sign or several but still have to be so grouped, the common link being *the state of the heart and its reserve force*, which is slightly affected.

Stage II.

While the out-patient room is daily crowded with patients in the first stage, cases in the second stage are comparatively rare. When 400 cases had been examined the proportions were: Stage I., 85 per cent.; Stage II., 4 per cent.; and Stage III., 11 per cent.

Complaint on admission.—In addition to the symptoms described under Type I. a history of anginal-like attacks can be obtained. A common story of a patient is this: "On the slightest exertion, especially after meals, a devil takes hold of my throat and chest; I cannot breathe, I imagine my end has approached, but I cannot say the last word of my prayers. This lasts a few minutes." In some cases which I have actually observed during the attack it was followed by an area of tenderness in the left mammary region and the ulnar side of the left arm and forearm.

Physical signs.—The apex beat is now in the nipple line or slightly outside it. The deep cardiac dulness is definitely increased at the fourth interspace. The apex beat is of a heaving nature; the murmurs are more distinct than in Stage I., though of the same character. The chest circumference at the same level measures 96–102 cm. The pulse rate at rest is 105–115 per minute, the respirations are 25–35, and the blood pressure is 140–160 mm. Hg. The sphygmographic tracing shows the characteristics of high-tension pulse.

The skin over the left breast is very sensitive and touching the hairs may be painful, most marked at the second intercostal space. The left arm, especially the radial side, is also tender. There are no such areas at the back nor on touching the muscles in the neck. When the patient is asked to walk 50 to 100 metres the pulse rises to 130 and the respirations to 60, and he has to sit down breathless and giddy. There are no œdema and no enlarged liver; the urine is free of albumin. Attacks of angina were observed in the hospital. They are neither severe nor frequent in any one case, the pain radiating most commonly to the ulnar side of the left forearm.

Stage III.

The patient is pale and dropsical, more commonly a child. He is unable to make any exertion; sometimes sitting or standing up causes breathlessness. The pulse is 120–130 per minute, small and readily compressible; the blood pressure is either 100–110 or 120–140 mm.Hg. The apex beat is outside the nipple line, with an increased area of deep cardiac dulness, but in some no such increase could be made out, and the apex beat, which is hardly felt, lies 1 cm. or more inside the nipple line. Cardiac murmurs are now no longer roaring, and in a third of the cases are absent at the apex and slight at the pulmonary area. A murmur at the jugular bulb was absent in 9 cases out of 20. There are an enlarged liver and œdema of the lungs. The urine may contain albumin, sometimes merely a trace. Cases that showed casts on examination were excluded. Areas of hyperalgesia were present, but not marked as in Type II. No attacks of angina observed, but in 20 per cent. of the cases a history of such could be obtained.

How the Circulation is Carried Out.

Efficient circulation normally depends on—(1) the pressure of the blood in the capillaries; (2) the velocity of the blood in the same; (3) its volume; and (4) its quality.

In anæmia the volume of blood is increased. This volume has to be accommodated in the circulatory system. The arteries, arterioles, and capillaries dilate, evidenced by (1) the size of the radials, (2) capillary pulsation, and (3) the free flow of blood from the pricked finger. With a blood pressure not above the normal the smaller arteries dilate more than the larger ones.

The chest enlarges and the suction action of the thorax is increased. This is more marked in chronic than in acute cases. The condition is one of hypertrophy of the lungs, not emphysema. The breath sounds are not diminished and expiration is not prolonged. The amplitude of respiration is increased. Bronchitis is a very rare complication. Post mortem there are no signs of emphysema. The pulmonary vessels dilate, and the right side of the heart being more extensible than the left is also engorged. Enough evidence is shown in the accentuated or doubled second sound at the pulmonary area.

The output of the left ventricle, judging from its size and the difference between systolic and diastolic blood pressure, is not increased, but the rate of contraction is, and the output per minute must be above the normal. With an arterial pressure almost normal the heart must be overtaxed, but as can be seen clearly from the symptoms there is no depression of tonicity in 8 cases out of 10. The presence of symptoms such as breathlessness, palpitation, &c., on exertion is alone not evidence of dilatation but of diminution in the field of cardiac response, and, in other words, partial exhaustion of the reserve force of the heart. The poor quality of the blood must play a part in the production of these symptoms on exertion.

With the continuance of the anæmia the arterioles begin to contract, possibly due to stimulation of the vaso-motor centre, and Type I., already described, drifts into Stage II. The contraction occurs at first in temporary attacks, later becoming permanent, the blood pressure then rises, and the veins become relaxed though not engorged. Further extra work is thrown on the left ventricle, with marked embarrassment evidenced by areas of hyperalgesia, attacks of angina, and physical signs of cardiac dilatation. The heart is able to maintain an efficient arterial pressure in the recumbent position, and evidence of non-efficiency of the circulation is not apparent in other organs. Stage II. drifts to Stage III., where the arterial pressure can be no longer maintained and severe effects follow. Type II. is rare and occurs in cases exposed to prolonged and especially recurrent infections. The same patient may have been to the hospital on two or more occasions before. When heart failure supervenes on this type the blood pressure may be kept up above normal for some time, and there is always the previous history of anginal attacks, but when failure follows Stage I. the blood pressure is not raised and there is no such history of cardiac pains. Dropsy is extensive and the hæmoglobin is generally very low (10–15 per cent.). Such cases are more common in children.

Post mortem the two types of hearts—(1) the hypertrophied fatty left ventricle, and (2) the small fatty left ventricle—are too well known.

The Origin of the Mitral Murmurs.

Many hypotheses have been offered. Before discussing a new one let us consider the factors that operate in preventing dilatation of the ventricles: 1. Tonicity of the heart muscle. This is most important. 2. The columnæ carneæ. The first and second classes of these are well-developed in the right ventricle. 3. The valves of the tricuspid orifice are rarely competent to close the opening (John Hunter). Mayo declared that the tricuspid valves never perfectly close the orifice. The pressure in the right ventricle cannot experimentally be much raised as the fluid leaks through the orifice. In the case of the left side the columnæ carneæ are very poorly developed, and the mitral valves are competent to close the orifice.

The left ventricle was shown to be overtaxed in cases of Type I., and with a poor blood-supply it is apt to dilate. This was shown not to be the case. Evidently some mechanism must be in operation if the wall does not yield. What is this safety mechanism? Normally the left ventricle is already partly filled before auricular systole, which is followed by closure of the mitral orifice, and before the ventricle has thoroughly set into systole. The vibration of the valves gives rise to the first sound. In anæmia the ventricle was shown to fill well during diastole and with the onset of systole is probably over-distended. The papillary muscles contract later than the rest of the ventricle, and their object is to prevent retroversion of the valve flaps into the auricle.

My hypothesis is this: The contraction of the papillary muscles if continued further will increase the convexity of the auricular surface of the flaps, which would be supported by the column of blood in the ventricle; further contraction would pull the valve edges into the ventricle, the latter at the same time separating. The chordæ tendineæ from each papillary muscle to both valves tend to prevent undue separation. The origin of the papillary muscles from the anterior and posterior walls, the two contractile walls of the left ventricle, may be a means of regulating their action according to the degree of distension and integrity of the muscle. A chink would be created between the valves—some blood would regurgitate, the overtension in the ventricle released, and possibly a more efficient contraction continued, but a murmur systolic in time results.

Some facts favour this safety-valve hypothesis: 1. The murmur is best heard or only heard in the recumbent position. In this the heart-rate is slowed, the diastolic period increased, the ventricle overfilled, and the mechanism is more needed. With the short diastoles of exercise the murmur often disappears. 2. The murmur resembles one of mitral stenosis in its conduction being localised to the apex or internal to it; a thrill is sometimes felt. Separation of the valves, as was shown, can at best be but slight, and the conditions simulating stenosis are present. The edges of the valves being pulled inside the ventricle the murmur is essentially intraventricular, and the chance of its conduction with the current of blood is slight. The character of the murmur differs from that of stenosis, for the surface of the normal valves over which the blood flows is also different from that in cases of stenosis. 3. The presence of (?) doubled first sound at the mitral is in a quarter of the cases apparently due to vibration of the mitral cusps consequent on overaction of the papillary muscle. When the condition advances a murmur is produced, and a case often passes from one stage to another and back again as conditions get better or worse. 4. Post mortem the papillary muscles taken from cases in the last stages are found to be very fatty, but undoubtedly increased in bulk out of proportion to the hypertrophy of the left ventricle. This is more apparent in the fresh state than in the stained condition. The increase in the size and number of fibres points to previous hypertrophy and past overaction. I had no opportunity of examining these muscles in cases in the earlier stages. 5. A similar murmur is heard in Graves's disease (before actual dilatation has set in), and in overstress of the heart from exercise when there is no sign of increase in the heart chambers. In these and other circumstances conditions obtain similar to those of anæmia which call for the safety-valve mechanism: (1) Over-tension in the left ventricle, either absolute or compared to the weak condition of the muscle; and (2) slight diminution of the reserve force of the heart, the tonus being hardly affected.

As in all protective reflex phenomena, the mechanism comes into play consequent on other sources of stimulation or an irritable nervous system. Hence the functional murmurs in the excitable hearts of the young; but even here over-distension of the left ventricle has been suggested by Mackenzie as possibly playing a part.

As regards the murmurs present in the area of the base, more than one kind have to be distinguished. 1. In rare cases an artery enlarges in the second and third spaces one inch outside the sternum, and pressure on it by the stethoscope causes a murmur. A similar one was described in arterio-sclerosis by Berghe. 2. A meso-systolic murmur roaring with forced expiration and varying with pressure. Pulsation, both systolic and diastolic, is often present in the same area. This is possibly due to a dilated pulmonary artery approaching the chest wall. 3. A murmur that has no relation to the respiration, or at least a very varied one, and may remain long after the apical murmur has disappeared. 4. A murmur having a definite relation to the mitral one and only disappearing with the disappearance of the latter or its conversion into a (?) first sound. I suggest that such a murmur is due to a slight kink that occurs experimentally in the aorta when the papillary muscles forcibly contract, pulling on the valves, as the fibrous ring to which the latter are attached is continuous with that into which the media of the aorta is inserted.

A CASE OF MOLLUSCUM CONTAGIOSUM CURED BY X RAYS.[1]

BY LIDBROOKE FRANK COPE, L.S.A.,
STAFF-SURGEON, R.N.

THE patient, a Krooman, was admitted to the Royal Naval Hospital, Simon's Town, with a group of little tumours situated just above the right elbow-joint. (Fig. 1.) Each tumour contained a soft central core from which there was an exudation consisting of serum, a few erythrocytes and cocci, together with the typical hard oval "molluscum bodies." In the occipital region he had a small hard tumour of the keloid type. The history was indefinite, the only information the patient could give being that he had noticed the place on his arm "for some time."

Treatment in the first instance consisted of fomentations with 20-grain doses of potassium iodide thrice daily, without any improvement whatever. After 10 days of this treatment it was decided to try the effect of X rays. The affected part was accordingly exposed to X rays for 10 minutes every other day. The condition at once began to improve, and at the end of the twelfth sitting had completely healed. The second photograph (Fig. 2) was taken 15 months later, and gives satisfactory evidence that the cure is permanent.

The chief points of interest in the case lie in the fact that in the pigmented skin of the negro it is not easy to see zones of inflammation, &c., such as give characteristic appearances to skin lesions in Europeans, and the rapidity with which the condition healed with X rays—a result quite in accord with those obtained by Norman Walker[2] and other dermatologists.

A DOUBLE MONSTER.

BY B. R. CHATTERTON, M.D. DUB., F.R.C.S. IREL.,
LIEUTENANT-COLONEL, I.M.S.

AT my request the following account of a double monster has been written by Mr. J. R. Mackenzie-Jones, I.M.S.

A Telin of village Fularia, P. S. Mirganj, gave birth to a double monster on April 9th, 1914. It was born alive and lived for three days, dying on April 12th.

A post-mortem examination was made on April 13th, when the creature was found to consist of twin fœtuses, united by their trunks and having two heads well covered with hair, four arms, and three legs, two in the front and one at the back with seven toes. The sex was female. There was one anus, near the leg at the back. (See Figs. 1 and 2.)

On opening the body the following were found and noted. Stomach, one and common; liver, common and obliquely extended from right to left; spleen, two; kidneys, two; bladder, one; intestines, common; sex (female), common; hearts, two; aorta, common; and lungs, four.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Localising Brain Symptoms as Early Events in Tuberculous Meningitis.—Demonstration of Cases and Specimens.

A MEETING of this section was held on May 28th, Mr. T. H. KELLOCK, the President, being in the chair.

Dr. C. O. HAWTHORNE read a short paper on Localising Brain Symptoms (Hemiplegia and Hemispasm) as early Events in Tuberculous Meningitis.

Dr. HAWTHORNE also showed a case of Hemiplegia in a girl aged 10 years, with sudden onset but without convulsions, and no evidence of visceral disease. There was a history of good health prior to April 4th. On that day the mother left the child sitting on a chair by the fireside, and when she returned shortly afterwards found her lying on the floor paralysed on the right side and unable to speak plainly. She did not observe anything in the nature of a fit or convulsion. When admitted to the hospital on April 8th the girl had right hemiplegia, was unable to talk plainly, and had a temperature of 103° F. Examination otherwise negative, and cerebro-spinal fluid apparently normal. The temperature fell to normal the next day, and the paralytic condition soon began to improve.

Dr. ERIC PRITCHARD exhibited the following cases: 1. A case of Cystic Lymphangioma in an infant, which he had shown to the section on Jan. 23rd, 1914, as one of persistent "caput succedaneum." Subsequent events proved that this view of its pathology was incorrect, and that the tumour was probably a congenital cystic hygroma or lymphangioma in an unusual situation. At the time the diagnosis was obscured by the fact that the tumour was the presenting part (left shoulder presentation) and that the contents of the cyst, which were drawn off by hypodermic needle, consisted of a blood-stained fluid like blood serum. The tumour had continued to increase in size *pari passu* with the growth of the infant. 2. A case of Polio-encephalomyelitis. The patient, a healthy boy aged 7 years, developed a squint and double vision on April 27th. He was brought to hospital on May 3rd, when he was examined, but no other lesion could be discovered. On May 8th the parents noticed weakness in the right arm and dragging of the right leg. On the 10th he was brought again to the hospital, and then complete palsy of the sixth left nerve was discovered. No nystagmus; discs normal; partial paralysis of the right twelfth nerve. Shoulder girdle: Some weakness of the right side. Arms: No wasting of arm and hand muscles, temperature of both the same; weakness of right arm and hand; grip poor on the right; the right thumb and fifth finger could be opposed only with difficulty; jerks +, more so on left side. Abdomen: Reflexes on left side active, absent in upper half on the right side; no wasting. Legs: No wasting; the right leg and foot colder than the left; weakness of muscles; knee-jerks active on the right, exaggerated on the left; no ankle clonus; ? extensor response on right, flexor on left. On the 14th the boy was admitted to hospital. New lesions were found to be present. Seventh nerve palsy (incomplete type) on the right side; eighth nerve affected; partial deafness; taste normal. Arms: No wasting; grip on the right side weaker than the left; jerks exaggerated on the right, active on the left; total inability to oppose thumb and fifth finger; marked dysdiadokokinesis on the right side. Abdomen: Reflexes absent on the right side. Legs: Weakness greater on the right side; the right colder than the left; knee-jerks, clonus on the right, exaggerated on the left; no ankle clonus; Babinski's sign on the right side, flexor response on the left. No spasticity. Incoördination in walking. No Rombergism. Sensation to light and painful touch on right leg and foot slightly diminished, otherwise normal.

Dr. H. THURSFIELD showed a child with Contraction of Limbs—a case for diagnosis. The child was aged 8 months, with asymmetry of head and chest. The thumbs were flexed into the palms of the hands, and the legs were flexed at the knee-joints and could not be fully extended. There was talipes of both feet. The patient was the fourth child, born at full term, the labour being natural. Three other children were alive. There had been no miscarriage. The mother had been quite healthy during pregnancy.

[2] Medical Annual, 1906, et seq.

Dr. J. D. ROLLESTON showed a case of Ectrodactyly in a girl aged 3 years. The right upper arm and forearm were of the same size as the left, but the right hand was rudimentary. The right metacarpus was 2·5 cm. long by 4 cm. broad, the left 5·5 cm. by 6·5 cm. broad. The phalanges of the right hand were represented by five small tubercles; the thumb tubercle was the largest, being 9 mm. in length, and alone carried a nail, the little finger was 2 mm. long, and the second and third fingers only 1 mm. long. The thumb rudiment and, to a less extent, the other tubercles were movable at will; there was no trace of a scar. The left upper limb and both lower limbs were normal, and there were no other external deformities nor apparent visceral anomalies. Apart from the ectrodactyly the child was well developed. The parents and two other children in the family presented no deformity. The mother attributed the patient's deformity to having seen, during the fourth month of pregnancy, her eldest daughter catch her fingers in a mangle. The girl escaped with slight bruising of the fingers, and the mother did not anticipate the deformity of her child.

Dr. E. G. L. GOFFE showed a case of Syndactyly of the Left Hand with Constriction of the Right Forearm in a girl aged 4 years.

Dr. F. E. BATTEN and Dr. MILDRED A. JUKES showed a case of Amaurotic Family Idiocy (Waren Tay-Sachs Disease) in an infant, aged 11 months, born of Jewish parents at full term, and apparently normal at birth. Weakness of the arms and legs was soon observed, and at the age of three months the mother noticed that the child was blind. The child was the youngest of eight; one sister, similarly affected, died in infancy one year ago. The child shown was a well-nourished child, but feeble; she could not sit up without support. There was no rigidity; all reflexes were normal. The child took no notice of her surroundings, lay quietly in bed, and was not irritable. There was some perception of light, otherwise the child appeared to be blind. On examination of the fundi, the typical white patch was seen on the maculæ with a central, cherry-red spot. The cerebro-spinal fluid was normal. The Wassermann reaction was negative.

Dr. PHILIP FIGDOR exhibited a specimen of Pericarditis in Diphtheria. The patient, a boy aged 3 years, was admitted to hospital for laryngeal diphtheria on Nov. 30th, 1914. Tracheotomy was performed shortly after admission, with instant relief. On Dec. 14th the cardiac rhythm became irregular. On Jan. 11th, 1915, a faint systolic murmur was heard at the apex. On Feb. 27th the cardiac dulness was greatly increased in both directions, and a soft ventricular murmur was heard at the apex, in the axilla and pulmonary area, and there was occasional reduplication of the second sound. On March 1st the murmur was heard in all the areas, but best at the apex. The cardiac dulness was slightly decreased on the right. On March 5th the general condition of the patient was much worse; cyanosis was marked. The cardiac dulness was greatly increased in both directions, and a harsh, double murmur was heard in all the areas. A diagnosis of pericarditis was now made. On the 8th the cardiac dulness was considerably reduced. A mid-diastolic murmur was heard within the apex. By the 15th the cardiac dulness was again greatly enlarged, and death took place on the 23rd. Post mortem the parietal and visceral layers of the pericardium showed recent pericarditis. There were about 10 ounces of serous pericardial fluid. Mitral valve: Edges thickened and eroded. Aortic and pulmonary valves healthy. Left ventricle hypertrophied; right ventricle slightly hypertrophied. Great œdema of pericardium and tissues at root of neck, including the thymus. Lungs almost airless; no tubercle; no evidence of consolidation. Very little fluid in pleural cavity. Slight œdema of mesentery. Gall-bladder œdematous, walls being about one-third of an inch thick.

Dr. F. LANGMEAD showed a case of Hypopituitarism in a boy aged 19 years and 3 months. He was extremely obese, and his general development, mental and physical, resembled that of a boy of 11 or 12 years. The genitals were rudimentary. There was no hair on the face, but some in the suprapubic region. The breasts and general development were of the female character. The voice did not appear to have broken. The amount of urine passed varied between 104 and 260 ounces per diem. There was a corresponding polydipsia. The optic discs and fields of vision were normal. The blood pressure ranged between 110 and 130 mm. Hg. Sugar tolerance had not been tested adequately. The diagnosis was established by a skiagram of the pituitary fossa, which was seen to be minute, the anterior clinoid processes being greatly thickened.

ROYAL ACADEMY OF MEDICINE IN IRELAND.—The Section of Anatomy and Physiology of the Royal Academy of Medicine in Ireland met in Queen's College, Belfast, on May 28th. In the Anatomical Department Mr. P. T. Crymble showed a large number of skiagrams, stereoscopic views, and so on, and the new X ray equipment installed for use in the Department of Anatomy. Professor J. Symington exhibited casts of the cranial wall and of the brain and its membranes in the Museum of Human Anatomy. He also contributed a paper dealing with Some Additional Observations on the Estimation of the Degree of Brain Development from Endocranial Casts, and he gave a description of a new model to illustrate cranio-cerebral topography. In the Physiology Lecture Room Dr. J. A. Milroy read a paper on Some Applications of Electrolytic Reduction. Dr. J. E. McIlwaine read a communication on the Electrocardiographic Method of Estimating the Condition of the Heart Muscle. Dr. J. M. Gibson read a paper on Heart Block produced by Yohimbin and Quebrachin. Professor T. H. Milroy contributed a paper on the Action of Rennin, Professor W. H. Thompson on the Effect of Racemic Arginin on the Excretion of Creatinine and Creatine, and Professor B. J. Collingwood on Some Further Observations on a Urinary Acid Index. On May 29th the members of the section interested in physiology visited the Royal Victoria Hospital, Belfast, where Dr. McIlwaine showed the electrocardiograph and demonstrated its great usefulness in diagnosis and prognosis. This instrument has been in practical use for over a year and a half, and is the only one in Ireland.

NORTH STAFFORDSHIRE MEDICAL SOCIETY.—A meeting of this society was held on May 27th at the North Staffordshire Infirmary, when the following cases and specimens were shown among others. Dr. A. Gill and Dr. A. Hilton John: Transposition of the Viscera in a man aged 23 years.—Dr. S. King Alcock: A specimen of "Anguillula Aceti" in Urine.—Mr. E. E. Young: A man, aged 63, from whom the right half of the tongue was excised for Epithelioma on June 28th, 1912, the glands in the anterior triangle being removed on July 15th, 1912; apparent cure.—Mr. Harold Hartley: (1) Living case, Cancer of Tongue, operated upon; and (2) pathological specimen, Strangulation of the Undescended Testis.—Dr. A. R. Moody: A case of Miners' Nystagmus.—Dr. F. Shufflebotham: A case of Miners' Nystagmus aggravated by Incipient Cataract.—Mr. George A. Carter: Two cases of Nasal and Pharyngeal Syphilis, showing the result obtained by treatment with intravenous injection of "606," followed by intramuscular injections of mercury.—Mr. R. H. Dickson: Cases of Entropion and Trichiasis, showing results of treatment by Transplantation of Buccal Mucous Membrane.

THE annual meeting of the Medico-Psychological Association of Great Britain and Ireland has been fixed for July 22nd, and will be held in London.

BRIDGWATER INFIRMARY.—At a special meeting of the subscribers held recently to consider the serious financial condition of this institution it was stated that an extension of the infirmary was now being carried out at a cost of £6000, towards which sum £4000 had been taken from reserve funds, which meant a loss of £160 per annum in the income. The donations of workpeople had decreased yearly from £275 to about £42. It was eventually decided that in future a charge must be made for all patients—viz., for in-patients 3s. weekly and for out-patients 1s. weekly, patients under 14 years of age to be charged half that amount. Accidents would be admitted free as hitherto.

Reviews and Notices of Books.

Human Physiology.

By Professor LUIGI LUCIANI, Director of the Physiological Institute of the Royal University of Rome. Translated by FRANCES A. WELBY. With a Preface by J. N. LANGLEY, F.R.S., Professor of Physiology in the University of Cambridge. Vol. III.: Muscular and Nervous Systems. Edited by GORDON M. HOLMES, M.D. Dub. London: Macmillan and Co., Limited. 1915. Pp. 667. Price 18*s.* net.

VOL. I. of this work was reviewed in THE LANCET, July 1st, 1911, and Vol. II. on June 7th, 1913. This volume brings the subject matter up to 1913. In 1913 Professor Luciani received a commemorative medal and an album containing the autographs of almost all the world's most eminent physiologists as a mark of his colleagues' esteem and as a tribute to the excellent and brilliant researches carried out by himself during a period of at least four decades. Dr. Gordon Holmes acts as editor in place of Dr. M. Camis, who is unable to act again in this capacity. At the outset let us say that Miss Welby has done her part most efficiently. The translation runs smoothly and does her much credit.

The first three chapters deal with the Muscular Systems. Over 90 pages are devoted to the general physiology of muscle. In this, as in all succeeding chapters, the historical touches in the text are peculiarly valuable. They show the author's erudition, his wide knowledge of the subject, and give that indefinable setting to the actual facts which raise this work to something more than a mere text-book of bald facts and current theories. Moreover, the critical acumen of the author reveals itself in almost every chapter. The matter in the chapter on muscle follows more or less conventional lines, but there are many details and acute observations incorporated which are not found in the ordinary text-books. Since 1871 Luciani has always had his own views as to the relaxation phase of a muscular contraction, skeletal or cardiac. Those interested will find his position elucidated in the text. Rigor mortis is more than a mere coagulation process. In mammals, at least, it is due to loss of oxygenation owing to arrest of the vascular circulation, so that according to Winterstein it is an asphyxiation phenomenon. The little-known ergograph of Treves—little known or at least little used in this country—is fully described. An all too short description of Einthoven's string galvanometer is given. A figure of the instrument and electrocardiograms would have been more illuminating. Langley's "receptive" substances are mentioned in the bibliography, but little is said of them in the text. We heartily welcome the chapter on mechanics of locomotor apparatus (pp. 96–128), a subject all too much neglected and even omitted in some of our English text-books. It is a subject requiring distinct anatomical as well as physiological knowledge. Luciani has made ample use of the work of Braune and Fischer. He was conversant with this work in his Leipsic days. The work of Marey, Carlet, and the French school is also incorporated. Phonation and articulation are the subjects of Chapter III. (pp. 129–174). This chapter has been considerably abridged. It appears that while Grützner used carmine to determine the impression left by the tongue during the articulation of certain sounds, Luciani and Baglioni used cocoa powder.

The remaining part of the text deals with the Nervous System. First, the general physiology of the nervous system is considered (pp. 175–277); its structural elements, the theory of independent neurones and its opposite, that of continuity of neuro-fibrils. Both theories are carefully expounded, exemplified, and criticised; the laws, rate of conduction, and the diphasic character of a nerve impulse, excitation of a nerve, its metabolism and electro-motive phenomena, electrotonus, and allied subjects. Full justice is done to the results obtained by Golgi, Cajal, Nissl, Apáthy, Bethe, and others. The neurone theory, it is stated, "is not based on any conclusive evidence." It is known that a nerve requires a supply of oxygen to keep up its vitality. But no one has yet proved that the oxygen absorbed and the CO_2 given off depend directly upon the state of rest or activity of the nerve. It is because nerves have a low metabolism and specific differentiation that they represent a form of living protoplasm which is endowed with peculiarly high resistance to noxious influences. The motor end-plates lose their conductivity long before the nerve fibres themselves. The most striking demonstration of the vital resistance of nerve is its comparative freedom from fatigue. The discussion on degeneration and regeneration of nerves is interesting, and we are glad to see an excellent exposition of the elaborate and careful work of Perroncito, of Turin (1908), who used Cajal's photographic method. English surgeons who have sutured and "crossed" two different nerves do not seem to be mentioned, though the work of Purpura in the same sphere is given in detail. Nor is much said of the observations of Head, Rivers, and Sherren. Perhaps this is reserved for a later volume.

The fifth chapter deals with spinal cord and nerves (pp. 278–358). Due credit is given to Galen, and the story of Bell, Magendie, Johannes Müller, Panizza, Longet, and Claude Bernard in relation to the functions of the nerve roots is told effectively. Justice is also done to the epoch-marking work of Sherrington on reflexes and allied phenomena and to the compensatory action of the cerebral hemispheres, where there is loss of afferent control in animals with paralysed sensibility. Metamerism, segmental skin-fields and their overlaps, the physiological unit of cutaneous metamerism—the dermatome, myelomeres, and "facilitation" are all fully discussed. The author regards it as far from certain that the psychical functions are localised exclusively in the brain, and he gives his reasons (p. 311). As to the knee-jerk, its reflex nature was clearly brought out by Sciamanna in 1900, although it should be stated that its true reflex character is not universally admitted. In any case it faithfully follows the oscillations in spinal excitability, hence its clinical value as a very delicate physiological indicator of the tone of the nerve centres in general, and those of the cord in particular. The data as to "trophic nerves" are carefully collated and sifted. Independent nerves of this class do not exist—i.e., there are no special trophic nerves and centres entirely distinct from the sensory and motor. A short chapter (VI.) (pp. 359–379) suffices for the sympathetic system. Chapter VII. (pp. 380–418) is devoted to the medulla oblongata and cerebral nerves. The cranial nerves are pretty fully dealt with as befits their importance. Some additional clinical phenomena dependent on lesions of them in disease would have been helpful.

Chapter VIII. deals with the hind brain (pp. 419–485) very fully indeed. This is not to be wondered at, having regard to the important and now classic contributions (1891) which the author himself has made to the physiology of the cerebellum. He does not subscribe to the doctrine of Stefani, that it is an organ for equilibration and orientation of the body in relation to its environment. Much stress is laid on the work of Bolk from a purely morphological point of view, and on that of Van Rynberk from an experimental standpoint. There is no decisive argument for localisation in the cerebellum, though some experiments on monkeys harmonise well with the localisation indicated by Bolk. The mid-brain and thalamencephalon are next discussed (pp. 486–526), and the effects of removal of the cerebral hemispheres in the lower and higher vertebrates. The last chapter (X., pp. 526–633) is consecrated to the fore-brain, its general anatomy, structure of the pallium, history of cerebral localisation, the excitable zones and localisation in dog, monkey, and man, and the physiological analysis of the motor reactions of the cerebral cortex association and other areas, basal ganglia, and speech. As to the histology of the pallium—its myelo-architecture and cyto-architecture—the work of Brodmann is followed rather than that of Campbell.

As to function, Haller (1708–77) regarded the *white* matter—*sensorium commune*—of the brain, not the grey cortex, as the seat of sensation and source of movement. But of all the astounding theories advanced that of the anatomist Sömmering is the most preposterous. In 1796 he localised the seat of the *pneuma psychicon* in the cerebral ventricles. More strange still, he concluded that the *aqua ventriculorum cerebri* is the single medium of nervous activity, the *sensorium commune*, the organ and seat of the soul. He dedicated his treatise to Kant—Kant of Königsberg, of Scottish origin, who in 1781 had published his chief work, "Critique of Pure Reason," and was professor of philosophy in his native town. His lifetime covers the period 1724 to 1804. We seem to be switched back to the middle of the sixteenth century and to Crooke's "Microcosmographia" (1616). In Vicary's "Anatomie of the Bodie of Man," regarding the "Ventricle of Memory," we read: "In the foremost Ventricle are the Five Wits; also the Fancy and the Imagination. In the 2nd or middle Ventricle is Thought. In the 3rd Ventricle is the Memory." Gall and Spurzheim are credited as the founders of the theory of cerebral localisation on the ground that they were the first who brought out the importance of the *grey matter* of the cerebral cortex in general. Gall later lost all critical sense in his eager attempt to solve his phrenological problems.

The alleged "inhibitory" reactions of the fore-brain and organic reactions of cortical origin and epilepsy and the functions of the sensory motor area are next described, analysed, and criticised. The two nuclei of the corpus striatum do not differ in function from those of the sensory motor area of the cortex. The visual area is fully and luminously dealt with. As to the other cortical centres—e.g., auditory—it is more difficult to obtain direct experimental proof. As to the pre-frontal lobes, it appears that their destruction in the dog and ape leaves these animals unaffected in any obvious way in regard to intelligence. "Clinical experience also militates against the theory which ascribes special value in regard to mental functions to the pre-frontal lobes" (p. 621). It is far otherwise with Flechsig's great posterior association areas—parieto-occipital areas. The facts of the morphology, anthropology, experiment, and clinical observations point to the special importance of this region in mental functions and memory itself. The parietal convolutions are extraordinarily well developed in men of high intelligence. Disturbances of speech due to cerebral causes—e.g., aphasia—are carefully analysed in the book, and the conclusion is arrived at that "Marie's cases do not invalidate Broca's theory. If carefully considered, it will be found that they are not irreconcilable with that theory, as shown by Mingazzini" (1908).

We have said enough to show the commanding interest and practical value of modern physiology as set forth in this volume by one of its most masterly exponents. New facts will be added daily, but this full account of the present aspect of physiology itself, as well as of its relation and applications to medicine and surgery, Luciani's "Human Physiology" ranks as a masterly exposition of the present state of a fundamental subject which, besides its importance in relation to medicine, allies itself with the moral sciences. The author recognises that psychical development, even on the ethical side, depends to a large extent upon the somatic substrate. We give a most cordial welcome to this volume, and express the desire and hope that the incubation period of the two volumes yet to appear may be largely diminished, but that will hardly be possible under present conditions. To each chapter is appended a short but useful bibliography. There is a double index—one of subjects and the other of authors. Oddly enough, though Cajal's name occurs in the text, it finds no place in the "Index of Authors."

Materia Medica and Therapeutics.

By J. MITCHELL BRUCE, M.A., LL.D. (Hon.) Aberd., M.D. Lond., F.R.C.P. Lond., and WALTER J. DILLING, M.B., Ch.B. Aberd. Tenth edition. London, New York, Toronto, and Melbourne: Cassell and Company, Limited. 1915. Pp. 645. Price 6*s*. 6*d*. net.

THE authors have taken the opportunity afforded by the new issue of the British Pharmacopœia to make a series of very radical changes in this text-book. The new standard has necessitated numerous omissions and additions, and the whole volume has been largely recast and rewritten. Since the type had to be completely reset, it was possible to alter the arrangement of the material, and the authors have, we think, acted wisely in adopting a pharmacological grouping of the drugs, instead of following the older lines of many former text-books. The new grouping necessarily has some disadvantages, since there are few remedies which do not merit a place in more than one group, and there are some whose claim to the position assigned to them is of the slightest.

An interesting section deals with questions of pharmacy. At the outset the various official preparations are defined and the methods of preparing them are given in useful detail. The directions concerned with practical pharmacy are clearly expressed and, although it is expected that the medical practitioner of the future will not have many opportunities to dispense his own preparations, the information afforded is sufficient to enable him to act on emergency. The few pages devoted to prescription writing are clear and concise.

The section relating to inorganic materia medica maintains the former grouping, based upon chemical composition rather than pharmacological action; thus the alkalies and alkaline earths, the heavy metals and metaloids, the non-metallic elements and acids are treated in separate groups. It is only when we reach the vegetable and animal materia medica and the synthetic preparations that the pharmacological grouping is really adopted; and in this connexion it is interesting to note that the authors retain the term "bitter tonics" to which objection has so frequently been taken by those who wish to restrict the term "tonic" to its purely physiological sense.

So far as the changes necessitated by the British Pharmacopœia are concerned the authors seem to have taken the actual words with a few unimportant omissions. The definitions and the characters are practically identical with those of the British Pharmacopœia. The omissions are mainly concerned with somewhat elaborate tests, which are of importance only to practical pharmacists.

The section devoted to therapeutics has been carefully revised, and many of the dogmatic assertions of former editions have been eliminated in accordance with modern views. A comparison of the information relating to syphilis in this edition with the corresponding paragraph in former editions will sufficiently indicate the care that has been taken to march in step with the times. A few diagrams have been introduced illustrating the action of various remedies on blood pressure, while two diagrams of electro-cardiograms serve to explain this method of investigation. The authors are to be congratulated upon the industry displayed in avoiding deviations from standard authorities.

Defective Children.

By Various Authors. Edited by T. N. KELYNACK, M.D. Vict., M.R.C.P. Lond. London: John Bale, Sons, and Danielsson, Limited. 1915. Pp. 462. Price 7*s.* 6*d.*

The aim of this book is to provide trustworthy and authoritative information with respect to the medical supervision and educational care of the chief classes of defective children of school age, in order that measures may be taken for the rectification, arrest, or amelioration of their disabilities. It is a book which will probably be of great use to school medical officers, but it is addressed also to medical advisers of all institutions concerned with the care of healthy as well as defective children. Most of the chapters are from the pens of recognised authorities, and all of them are valuable contributions to the special subjects with which they deal. There is no attempt made to separate physical from mental defects, probably a wise arrangement, since these two conditions are so closely interdependent. But accordingly chapters on paralytic cripples and tuberculous cripples are wedged in between others on criminal children and defects of vision.

The first chapter is concerned with the correlation of the public health services and administrative questions generally, and is contributed by Dr. E. W. Hope, the medical officer of health for Liverpool. This very important subject scarcely receives its due share of space. Dr. Hope condenses his remarks into ten pages, but some amends for brevity are made in a very excellent bibliography of references at the end of the chapter. This method of supplementing the many curtailments, which are imposed by the limits of the volume, is pursued throughout most of the chapters, and will be highly appreciated by readers requiring fuller information on special points. The chapters on the mentally defective child, idiots and imbeciles, and the epileptic child are respectively supplied by Dr. Hamilton C. Marr, Dr. Douglas William Hunter, and Dr. Andrew Fergus Hewat. The very important chapter on speech defects in childhood and early adolescence is contributed by Dr. L. H. F. Thatcher, and follows in close detail the methods and teaching of Professor J. Wyllie, of Edinburgh. Mr. Hastings Gilford's chapter on defective growth and development gives an interesting account of the rarer forms of abnormal development, including infantilism, ateleiosis, and progeria, but we venture to suggest that a wider view of the general principles concerned in the determination of anomalies of physical development would have been more in line with the general scheme of the work and more serviceable to the majority of readers. Important chapters are those on open-air schools, by Dr. Lewis A. Williams, and on schools for crippled children, by Mr. R. C. Elmslie. The interests of the deaf child are in the safe keeping of Dr. James Kerr Love.

Taking it all round, this is a very valuable addition to the rapidly growing library of the literature of medical school inspection.

Swanzy's Handbook of the Diseases of the Eye and their Treatment.

Edited by LOUIS WERNER, M.B. Dub., F.R.C.S. Irel., Sen. Mod. Univ. Dub. Eleventh edition. London: H. K. Lewis. 1915. Pp. xviii. + 646. Price 12*s.* 6*d.* net.

ANOTHER edition of this well-known text-book has been called for after an interval of three years. Since the last edition was published the original author, Sir Henry Swanzy, has died, and the revision has been carried out by Dr. Louis Werner, who had been associated with the author in preparing several of the previous editions. The present one retains all the characteristic features which have become so familiar.

The restoration of the chapter on the pupil, omitted in the last edition, is an improvement. The trephine operation for glaucoma has been dealt with at greater length, and there has been considerable revision of the sections dealing with vascular diseases of the retina. Other additions and modifications bring the book up to date, and it will doubtless retain its well-earned reputation as a reliable and convenient manual for students. The coloured plates are the same as in the last edition. The use of small print for the rarer conditions is a distinct improvement, but the retention of asterisks to signify subjects of intermediate importance seems unnecessarily elaborate.

MISCELLANEOUS VOLUMES.

Perpetual Peace: A Philosophical Essay. By IMMANUEL KANT, 1795. Translated with Introduction and Notes by M. CAMPBELL SMITH, M.A. With a Preface by Professor LATTA. London: George Allen, and Unwin, Limited. 1915. Pp. 203. Price 2*s.* net.—Although the nations are at war, the reissue of this translation in a cheaper form—it was first published in 1903—is opportune, for, as Kant points out, the mere cessation of hostilities is no guarantee of continued peaceful relations unless a guarantee is given by each individual to his neighbour. With Kant perpetual peace is an ideal to be sought after, and his essay is devoted to the consideration of the best means, founded on mutual interest, of pursuing that ideal. Miss Campbell Smith, who had the help of Mr. David Morrison, M.A., in revising the translation, has accomplished a by no means easy task, and, to quote the closing words of Professor Latta's preface, "Her work will have its fitting reward if it succeeds in familiarising the English-speaking student of politics with a political essay of enduring value, written by one of the master thinkers of modern times."

The motto "Laugh and the World Laughs with You," which is placed on the title-page of *Round the World in Strange Company*, by NICOLAS EVERITT (London: T. Werner Laurie, Limited. Pp. 283. Price 12*s.* 6*d.* net), exactly expresses the spirit in which Mr. Everitt writes about his travels in the United States and British Columbia. His racy descriptions of men and things are amusing, but his contrast of English and American custom-house methods in favour of the American does not ring wholly true. The book is full of humour and makes excellent reading.——Mr. JEFFERY FARNOL is a sound story-teller. In *The Chronicles of the Imp* (London: Sampson Low, Marston, and Co. 1915. Pp. 219. Price 3*s.* 6*d.* net.) we have a love theme, but the main interest of the romance centres round a boy, who sustains in divers times and places the characters of mediæval heroes, legendary personages, and pirates, with all the intensity of conviction characteristic of the imaginative child. Most of the action takes place in the open air, though the Borrovian element which marks some of Mr. Farnol's other books is absent. To those who can enter with sympathy into the romantic mind of childhood the book will prove delightful, but Mr. Farnol has better work to his credit.

An introduction briefly referring to the characteristics of the early herbalists, followed by a number of curious receipts, has been written by FLORENCE HINE, under the title of *A Chaplet of Herbs* (London: George Routledge and Sons. 1915. Pp. 168. Price 2*s.* 6*d.* net), who evidently enjoys browsing among old herbals. A longer introduction would have been an advantage, but it would be ungenerous to complain when such copious extracts that follow on "old-fashioned lore, gathered some of it from manuscripts which seem to have escaped the eyes of the curious, and the rest from books which have long slipped out of the memory of man," are given. There is an excellent bibliography.

In *Brazil, 1913* (Printed by Messrs. Butler and Tanner, Selwood Press, Frome, England. Pp. 604. Price 7*s.* 6*d.* net), Mr. J. C. OAKENFULL, the compiler, gives a very fair picture of Brazil in regard to its political and commercial position, together with information on its anthropology, ethnography, and history, as well as interesting descriptions of its fauna, flora, and geology. Appendices include a gazetteer, information as to cost of living, and a bibliography. The maps, plans, and illustrations greatly add to the value of this guide to a most important area of South America.

Egyptian (Arabic) Self-taught, by Captain C. A. THIMM, fourth edition, revised and enlarged by Major R. A. MARRIOTT, D.S.O. (London: E. Marlborough and Co. 1914. Pp. 80. Price 2*s.* 6*d.*), is a practical little handbook of colloquial Arabic as spoken in Egypt. It contains vocabularies of words in common every-day use and a selection of useful phrases. Professor Flinders Petrie has revised the proofs. The book should be a useful primer for the army and navy, travellers, missionaries, and traders in that country, which will doubtless be yet more opened up after the war.

While no books can replace the official Medical and Dental Registers, the various unofficial directories, by reason of their classification of names with regard to localities, greatly facilitate reference, and the *Dental Directory, 1915* (London: John Bale, Sons, and Danielsson. Pp. 236. Price 3*s.* 6*d.* net), which is now in its seventh year of issue and has been enlarged, is a most useful addition to works of this kind. Besides alphabetical and topographical lists of registered dentists in the United Kingdom, the Channel Islands, the Isle of Man, the colonies and abroad, information with regard to the L.D.S. curriculum is included, as well as much general information concerning universities, colleges, schools, hospitals, dental societies, and so forth.

JOURNALS AND MAGAZINES.

Quarterly Journal of Medicine. Edited by WILLIAM OSLER, J. ROSE BRADFORD, A. E. GARROD, R. HUTCHISON, H. D. ROLLESTON, and W. HALE WHITE. Vol. VIII., No. 31, April, 1915. Oxford: At the Clarendon Press; London, Edinburgh, New York, Toronto, and Melbourne: Humphrey Milford. Subscription price 25*s.* per annum; single numbers 8*s.* 6*d.* net each.—The contents of this number are: 1. Two Cases of Patency of the Ductus Arteriosus, by T. Wardrop Griffith. An interesting account is given of two cases of this developmental defect, in both of which the condition was recognised during life. One of the patients died from infective endocarditis, and the diagnosis was verified post mortem. In the other patient the signs were such as to suggest that there was some further anomaly of the great vessels, and possibly a developmental error giving rise to cyanosis, a symptom which is not usually met with in uncomplicated cases of patent ductus arteriosus. Dr. Wardrop Griffith discusses the causes and effects of this interesting abnormality. 2. Alterations in Arterial Structure and their Relation to Syphilis, by Hubert M. Turnbull. The normal structure of the arteries, the changes which occur during the growth of the individual, and the functions of the coats are considered, and then the abnormalities of structure are classified as follows: hypertrophies, degenerations, amyloid infiltration, inflammations, arteriosclerosis, aneurysm, and direct rupture. Each one of these changes is then discussed, more especially in regard to its causation and the part played by syphilis in this connexion. 3. Mumps: A Critical Review, by Anthony Feiling. An interesting summary is given of our knowledge in regard to this common infectious disease, together with a critical analysis of recent observations upon its pathology, bacteriology, and complications. Dr. Feiling incorporates some personal observations upon the blood in 42 cases of this disease. He shows that there is a slight increase in the total number of leucocytes, together with a lymphocytosis which is both relative and absolute, that this lymphocytosis is present on the first day of the disease, and persists for at least 14 days. He suggests that this blood change is of diagnostic value in differentiating mumps from other inflammatory swellings of the parotid or submaxillary gland. A bibliography extending to 98 references is given.

Cornhill Magazine.—In the June number of *Cornhill* Mr. Anthony Hope Hawkins contributes some observations in defence of the memory of his kinsman Lord Brampton, and, as in the case of Sir Herbert Stephen's vindicatory article in May, Sir Edward Clarke is given an opportunity to make an immediate, or simultaneous, reply. This, it may be observed, is a convenient plan when anything in the nature of a controversy takes place in a magazine published at monthly intervals. Mr. Hawkins argues that Sir Edward Clarke could have raised the question of Sir Henry Hawkins's judicial conduct in Parliament, and incidentally describes his uncle as a "conscientious, wise and a compassionate judge." We can leave Sir Edward Clarke to assert the difficulty of securing the removal of a judge from the bench for the kind of conduct of which he alleges Sir Henry Hawkins to have been guilty, but with regard to the passage cited it may be suggested that probably the quality of compassion, which the late judge no doubt possessed, overrode those implied by the other two epithets, with the result that he "got a verdict" which was not supported by the evidence. Sir Henry Hawkins was not a man to risk being publicly proved wrong if he could help it, but in the particular instance selected by Sir Edward Clarke he, no doubt, was led by sympathy with the victim to underestimate the weight of the medical evidence called for the defence and of the medical opinion behind it.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.—A meeting of the executive committee took place at the society's offices on May 21st, Dr. F. J. Allan being in the chair. During the first few months of the year the sickness claims were heavy owing to the influenza epidemic, but claims have since fallen to normal. It was reported that since the outbreak of war the society had paid the sum of £250 in claims arising from injuries received by members on active service. The number of the society's members serving in the Royal Army Medical Corps steadily increases, and much satisfaction has been expressed at the treatment accorded them by the society in respect of their sickness and accident benefits. In spite of the adverse conditions experienced among all insurance companies, the society is maintaining its new business. Prospectus and all information will be supplied by the secretary (300, High Holborn, W.C.).

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

TUESDAY, JUNE 1ST.

THE General Council of Medical Education and Registration began its summer session to-day at its offices, 299, Oxford-street, W. Sir **DONALD MACALISTER**, the President, was in the chair.

New Members.

Sir **BERTRAM WINDLE**, M.D., took his seat as representative for the National University of Ireland for three years from Dec. 10th, 1914; and Sir **ARTHUR CHANCE**, F.R.C.S.I., took his as representative of the Royal College of Surgeons in Ireland for one year from Feb. 5th, 1915.

An Apology for Absence.

A letter was read from Dr. Hepburn, in which he intimated that he was unable to attend the Council this session owing to his duties as a medical officer of the Western Command at Cardiff.

President's Address.

Sir **DONALD MACALISTER** delivered his presidential address. He said :—

My first duty is an agreeable one. I have in your name to welcome back to the Council two former members whose past services are still fresh in our remembrance. Sir Bertram Windle, from the National University of Ireland, takes the place of our late colleague Sir Christopher Nixon. Sir Arthur Chance, from the Royal College of Surgeons in Ireland, resumes his old seat, vacated in February last by Sir Lambert Ormsby on the completion of his term of office.

The Council will also be glad to see in his accustomed place our Registrar, Major King. After strenuous labours with his regiment at the front, Major King was invalided home some months ago. He has now sufficiently recovered from his disablement to be allowed to give us his services as Registrar during the session, pending the decision of the War Office as to his future sphere of military duty. During Major King's absence Mr. Cockington, as Acting Registrar, and the other members of the staff have carried on the work of the office with praiseworthy zeal and efficiency.

I have to record with regret the death, since we last met, of our former colleague, Mr. Thomas Bryant, who retired in 1904, after 13 years of service as Treasurer of the Council.

The stress of the great war is still urgent upon us all. The country's call for service and sacrifice has been heard and answered in every part of the Empire. The response from members of our own profession has been especially prompt and generous. Many thousands of our brethren have freely given themselves and their sons, postponing every other claim to the demands of national duty. Members of the Council are fully sharing both in the service and in the sacrifice. To those of our colleagues who are to-day mourning, in proud sorrrow, the loss of gallant and promising sons, we offer the tribute of our heart-felt sympathy. And we deepen our resolve to ensure, by every service within our power, that such sacrifices shall not have been made in vain.

The call for qualified physicians and surgeons to take up duty with the Forces has become more and more insistent with the growth of the new armies. Our professional reserves, at no time large, have been drawn upon to the full. Throughout the kingdom organised efforts are in progress for such a readjustment of civil practice as will liberate all who can possibly be spared for the medical service of the Navy and the Army. In these efforts the Scottish Emergency Committee and local committees of the British Medical Association, with the effective coöperation of members of this Council, have taken a leading part. The services of qualified women have been freely offered and accepted for many of the places that are now vacant at home. Senior students, enrolled in the combatant ranks, have been recalled by the War Office, and directed to complete their curriculum with a view to qualification for the Royal Army Medical Corps. Special qualifying examinations have been held by the licensing bodies for candidates whose curriculum was completed. And from overseas have come large numbers of our colonial colleagues, who are possessed of qualifications registrable in this country, and so are eligible for commissions in our army. By the opportune action of the Belgian Government and of the Privy Council the Executive Committee was enabled to give effect to the application of Part II. of the Medical Act (1886) to Belgium, with the result that about 60 Belgian doctors of medicine have become legally qualified to practise in Britain, and to occupy professional positions in public and other institutions.

From all these sources we have obtained timely and valuable help, but they must if possible be supplemented. If we are to make good the losses in the Army Medical Service we must accumulate larger reserves. The casualty lists, and, I am proud to add, the lists also of rewards for conspicuous gallantry, testify to the magnitude of these losses. We must endeavour to fill the vacant places by men whose training and skill can be guaranteed, and whose devotion is not inferior to that of their fallen comrades. We look with confidence to the medical schools and corporations to aid us in our endeavour to maintain, even in the present emergency, the standards of teaching and of testing which we regard as essential to efficiency.

The inquiries, to which I referred in my address last November, regarding the number of students actually in attendance on courses of medical study at the several schools, have shown that at the end of 1914 there were considerably over 1000 fewer than in 1913. The recall of senior students from active service to resume their professional studies has had a favourable effect on the fifth year, now drawing to a close; but we must expect during the next few years a falling off of some 250 per annum in the number who become qualified as medical practitioners.

In the same address I called attention to the fact that, from certain of the provinces of Canada, able and efficient surgeons were desirous of coming to the aid of the Mother Country, but were hindered by difficulties created by their local registration laws. Encouraged by the reception accorded to my remarks here and in Canada, I ventured to communicate with the various medical authorities concerned, and to point out once more the Imperial bearings of the question of reciprocity. The response has exceeded all my expectations. From Ontario, British Columbia, Saskatchewan, Manitoba, and Alberta have come messages, often by cable, stating that legislation has already been initiated for the removal of existing provincial restrictions; and that the provinces desire that reciprocity with this country may be established at the earliest possible date. When the necessary steps are completed, and I have reason to think that no obstacles need be apprehended on this side of the Atlantic, all the provinces of Canada will have severally entered into reciprocal relations with the United Kingdom. The way will then be open for the application of the Medical Act (1886) to the Dominion as a whole, as it is now open to the Commonwealth of Australia. Thus, by the concurrent action of the separate provinces, the Dominion Medical Act, whose operation has hitherto been restricted so far as Imperial relations are concerned, will assume a more comprehensive character, and the medical federation of the Empire will be at length accomplished. Canada possesses schools of medicine of the highest repute; and we may confidently count on receiving from them a further supply of graduates qualified in all respects for the medical service of the State, and legally entitled to practise in any part of His Majesty's Dominions.

The British Pharmacopœia, 1914, was duly published in accordance with your instructions on Dec. 31st. The first issue of 20,000 copies is nearly exhausted. Steps have been taken for the preparation of a second issue, in which a few typographical faults, noted in the first issue, have been corrected. As you are aware, the Pharmacopœia Committee endeavoured to adapt the work to the general requirements of the British Empire, and at the same time to harmonise its directions with those of the States which were parties to the international agreement of 1906. The reception accorded to the new Pharmacopœia, both in the British Dominions and in foreign countries, encourages us to hope that our efforts have in a large measure been successful. The Government of India has intimated that a special edition, such as was prepared in 1900 for Indian use, will no longer be necessary in that country. The Belgian

Government, notwithstanding its present difficulties, has courteously undertaken the duty of intimating to the signatory powers the publication of the British Pharmacopœia, and the manner in which effect has been given therein to the recommendations of the international agreement.

In India legislation for the better regulation of medical practice, already accomplished as regards certain of the Presidencies, is in course of extension. We have received official intimation of a proposed medical ordinance for the United Provinces; and of new regulations, by the Government of India, under which the educational and professional standards for the subordinate medical department will be considerably improved. This will probably form the subject of a report to the Council from the Examination Committee.

From the English Board of Education a communication has been received, from which it appears that there is now some prospect of the establishment in England of a central authority, charged with the coördination and supervision of secondary school examinations and the inception of a system of leaving certificates. Such a system has long existed in Scotland, to the manifest advantage of secondary education in that country. The Council in 1904 resolved: "That any well-considered plan which would tend to a diminution in the number of examinations in preliminary subjects of education, and to a unification of standard of those which remain, would meet with the hearty approval of the Council." The subsequent experience of the Education Committee and of the Council with reference to the recognition and supervision of preliminary examinations, has not been such as to suggest that a "well-considered plan" of the kind would be other than welcome now. I have referred the Board of Education's circular to the Education Committee in order that you may have its report on the proposals at the present session.

At the instance of the Dental Education and Examination Committee inquiries have been addressed to the dental licensing authorities and dental schools as to the suggested deficiency of registered dentists. The replies received indicate the prevalence of an opinion that the unsatisfactory state of the law concerning unqualified practice has a deterrent effect on candidates, and that the duration and stringency of the present curriculum do not constitute a serious obstacle. The committee will present to you a synopsis of the views expressed by the various authorities, and will report on the questions raised by Dr. Newsholme's motion of Nov. 26th, 1914.

Under the powers conferred by you on the Executive and Office Site Committees, these bodies have made satisfactory progress in the task of providing new and better accommodation for the medical and dental work of the General Council and the English Branch Council. The present site and buildings facing Oxford-street have been sold to advantage. A new site in Hallam-street, near Portland-place and New Cavendish-street, has been secured. Mr. Eustace Frere, A.R.I.B.A., has prepared a design for handsome and commodious buildings, which has met with your approval, and has been accepted for exhibition at the Royal Academy. A contract for the erection of the buildings has been made with Messrs. Chinchen and Co., who have undertaken to complete the work by Nov. 1st. The structure has already reached the first floor, and there is a good prospect that the Council may be able to enter into occupation of it by the end of the year. Much pains have been taken by your committee to ensure that the arrangements made for the disposal of the old building, which we have outgrown, and for the new premises, in which we count on carrying forward our work with greater efficiency and convenience, shall be profitable to the Council and adequate to its needs.

Certain financial adjustments, as between the General Council, the Branch Councils, and the Dental Fund, have been under the consideration of the treasurers and the legal advisers of the Council. You will probably think this a suitable opportunity to define more clearly than heretofore the relations of their accounts in respect of capital and current expenditure. Fortunately the financial position for the last year is a favourable one; for although the expenses of the General Council have been unavoidably increased by certain temporary causes, the income of the four Councils in the aggregate exceeds their total expenses by some £2300. The prospect of a greatly diminished income due to the falling off in registrations during the next four or five years, which we must face as an incident of the war, will make it wise to persevere in effecting economies wherever these are practicable.

I am happy to say that our judicial work at this session promises to be less exacting than usual, and that our sittings need not be prolonged beyond this week. In connexion with the enforcement of the penal provisions of the Medical Acts, our thanks are specially due to the Royal College of Physicians of Edinburgh for its public-spirited action in prosecuting two firms of unqualified persons, who conducted so-called practices in that city to the scandal of the civic authorities and of the profession. The penalties recovered have, by order of the Executive Committee, been remitted to the Royal College as a contribution towards the expenses it has incurred. The College, by undertaking this important service, has demonstrated anew its corporate interest in the safeguarding of the public health.

Appointment of Committees.

The following committees were appointed:—

Executive Committee.—The President, Dr. Norman Moore, Sir Henry Morris, Mr. Tomes, Dr. Langley Browne, Mr. Hodsdon, Dr. Norman Walker, Sir John Moore, and Sir Charles Ball.

Penal Cases Committee.—The President, Dr. Saundby, Mr. Tomes, Dr. Norman Walker, and Dr. Little.

Business Committee.—Dr. Norman Moore (chairman), the President, Dr. Norman Walker, Sir Henry Morris, and Dr. Little.

Pharmacopœia Committee.—The President (chairman), Dr. Norman Moore, Sir Thomas Fraser, Sir George Philipson, Dr. Cash, Dr. Caton, Sir John Moore, Dr. Barrs, and Sir William Whitla.

Finance Committee.—Mr. Tomes (chairman), the President, Mr. Hodsdon, Sir Henry Morris, and Dr. Little.

Dental Committee.—The President (chairman), Sir Henry Morris, Mr. Hodsdon, Mr. Tomes, and Sir Charles Ball.

Dental Education and Examination Committee.—Mr. Tomes (chairman), the President, Dr. Knox, Sir Henry Morris, Sir Arthur Chance, Mr. Hodson, and Sir William Whitla.

Students' Registration Committee.—Dr. Norman Moore (chairman), the President, Dr. Mackay, Dr. Langley Browne, Dr. Norman Walker, Sir William Whitla, and Sir Bertram Windle.

The Finance Committee's Report.

Mr. TOMES submitted the report of the Finance Committee. That report stated that the income of the General and Branch Councils for the year ending Dec. 31st, 1914, was £9850 14*s.* 6*d.* The expenditure was £7550 16*s.* 2*d.* Consequently there was a surplus of £2299 18*s.* 4*d.* The report went on to state that the income of the General Council showed an increase of £67 11*s.* 11*d.* An increased sum of £80 was received for colonial and foreign registration fees, but the interest on deposits at the bank was less. All the branches had increased receipts from registration fees; the English branch receiving £783 10*s.*, the Scottish branch £420 9*s.* 6*d.*, and the Irish branch £189 7*s.* 6*d.* more than in 1913, making a total increase of £1518 3*s.* 2*d.* At one time it was feared that during the next year or two the registrations might fall much below the average owing to the number of senior students who had gone to the war in various capacities, their qualification being therefore delayed. The War Office, however, had made efforts to send back to their studies all fourth and fifth year medical students, and it might therefore be hoped that the decrease would be less than was anticipated. The number of students registered was 1600, which was an increase of 120 over 1913, and compared favourably with the average of 1374 for the years 1911–1913. At the present day medical practitioners were in great demand, and were easily able to procure employment; probably this fact was being more fully recognised by the public.

Mr. TOMES, in commenting on the report, said it was satisfactory and it contained no recommendation to the Council. So far the diminution of income had not been felt. Some extra expenditure had been incurred owing to the meetings of the Executive Committee regarding the steps to be taken in connexion with the recognition of Belgian medical qualifications.

The report was adopted without discussion.

The Recognition of Belgian Qualifications.

The PRESIDENT submitted reports from the Executive Committee in regard to the admission of Belgian medical and dental practitioners to British registration. The report in regard to the medical practitioners stated that: "Part II. of the Medical Act (1886) having been extended by an Order in Council to the kingdom of Belgium during the continuance of the present war, the committee has considered the conditions under which medical qualifications granted in the kingdom shall be recognised for registration in the Foreign List of the Medical Register of the United Kingdom, and has adopted the following resolution: That so long as the Order in Council of Jan. 7th, 1915, remains in force, any person who produces evidence satisfactory to the Registrar that he has obtained the degree of Doctor of Medicine in the Belgian Universities of Brussels, Ghent, Liége, and Louvain, and is legally authorised to practise medicine, surgery, and midwifery in Belgium; and who satisfies the Registrar as to the other particulars specified in Section 12 of Part II. of the Medical Act, 1886, shall be entitled to be registered in the Foreign List of the Medical Register."

The PRESIDENT said that, as he had already mentioned in his address, between 50 and 60 Belgian medical men had taken advantage of this opportunity to register, and others were coming forward.

The report was formally received.

With regard to Belgian dental practitioners a separate report was submitted. It was in the following terms: "The Executive Committee at its meetings on Jan. 22nd, 1915, and Feb. 22nd, 1915, as a matter of urgency arising out of circumstances connected with the war, instead of remitting the question to the Dental Education and Examination Committee for consideration and report to the General Council in the usual way, considered the question of the recognition of Belgian diplomas in dentistry and dental surgery. The committee at the latter late had before it official information in regard to the course of dental professional study and examination which had been furnished by the Belgian Minister of the Interior, and adopted the following resolution:—

(*a*) That a person who has attained the grade of Candidate in Medicine at one of the four Belgian Universities of Brussels, Ghent, Liége, and Louvain, and has, after pursuing the further course of study prescribed for dental practitioners, passed the Diploma examination held by a Belgian Provincial Medical Commission, shall be entitled to be registered in the Foreign List of the Dentists Register, provided he produces to the General Registrar satisfactory evidence in regard to the particulars set forth in Sections 9 and 10 of the Dentists Act, 1878.

(*b*) That, in view of the urgency of the matter, this resolution (*a*), adopted by the committee on behalf of the Council, become at once operative as an instruction to the Acting Registrar; and that the resolution be reported to the General Council for confirmation at the June session."

The PRESIDENT remarked that the information which the Executive Committee now had was that persons who since 1899 had passed the examination which was now prescribed for dentists, were eminently worthy of recognition.

The report was received and the resolution of the Executive Committee was confirmed.

Dental Cases.

The Council considered the reports of the Dental Committee in regard to certain dental practitioners.

The first case was that of Valleck Cartwright Mallan, who was registered in the Dentists Register on Dec. 6th, 1878, as "in practice on July 22nd, 1878." A previous report of the Dental Committee dealt with the manner in which his practice at 106, Edgware-road, had been conducted.

In their present report to the Council the committee found that the following facts were established by the evidence:—"Since the last hearing the said Valleck Cartwright Mallan has removed the tickets, newspapers, advertising letters from patients, and photographs from the doorway and window of the premises, and he put in a photograph of the premises as they now are. He stated that he has also entirely discontinued advertising his practice by means of circulars, pamphlets, or newspapers, by hand or through the post. The complainants offered no evidence that the said Valleck Cartwright Mallan had not fulfilled the undertaking which he had given to the Council."

The complainants, the British Dental Association, were represented by Mr. R. W. Turner, counsel.

Mr. Mallan attended.

After deliberation the Council decided not to erase Mr. Mallan's name.

The next case was that of George William Hammond.

The Dental Committee reported that: "The said George William Hammond was registered in the Dentists Register on Dec. 31st, 1878, as 'in practice on July 22nd, 1878,' and his address in the Register for the current year is 56, Kennington Causeway, S.E. Mr. Hammond did not attend. The solicitor proved the posting of the notice of inquiry on May 8th, 1915, by registered post to him at 56, Kennington Causeway and to Dental House, Ripon, his previous registered address. In both cases the notice was returned through the dead letter office. There is, in fact, no such place as Kennington Causeway, and Mr. Hammond no doubt meant Newington Causeway, near Kennington. Inquiry at 56, Newington Causeway (a common lodging house) elicited the information that although Mr. Hammond was well known and had stayed at that address he was not staying there then, but would probably be found at Rowton House, Newington Butts, where the notice of inquiry was forwarded with a covering letter by registered post on May 17th, 1915, and has not been returned. The committee find that the following facts were established by the evidence: That on Oct. 10th, 1912, the said George William Hammond was convicted at Ripon of felony, and that he was fined £1 and 7*s.* 6*d.* costs, or one month's imprisonment with hard labour in default. He was received into prison in respect of this conviction on Nov. 25th, 1914, and it was notified to the Registrar on Nov. 27th, 1914. The evidence before the committee consisted of the certified copy of the said conviction and of the due posting of the notice of inquiry on the dates mentioned."

Mr. Hammond did not attend.

After consideration *in camerâ*, the PRESIDENT said: I have to announce that George William Hammond having been proved to have been guilty of the felony alleged against him in the notice of inquiry, the Registrar has been directed to erase his name from the Dentists Register.

The Council adjourned.

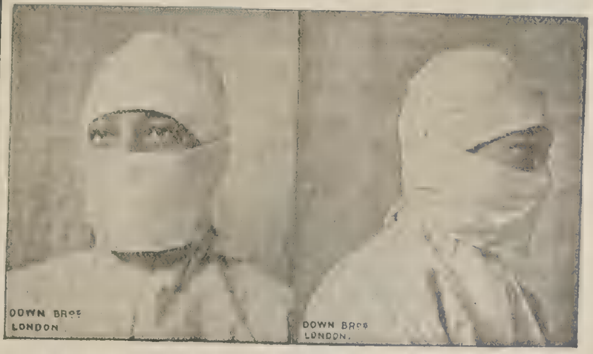
WEDNESDAY, JUNE 2ND.

The Council considered charges against medical practitioners during the whole of the sitting.

New Inventions.

COMBINED OPERATION CAP AND MASK.

THE illustration represents a form of combined cap and mask which will be found exceedingly convenient in practice. It is made in one piece, and is adjusted in the following manner. After putting the cap on the head the long tail-piece is passed across the face and fastened by buttons behind. The advantages are:—(1) More comfortable, no dragging on the ears; (2) it is fastened by buttons and therefore more easily secured; and (3) there is a slit in the cap behind which ensures the cap fitting accurately when the mask is pulled across the face.



The makers are Messrs. Down Bros., Limited, 21 and 23, St. Thomas's-street, London, S.E.

E. J. O'MEARA, F.R.C.S. Eng.,
Major, I.M.S.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

GLAND PREPARATIONS, VACCINES, AND NUCLEO-PROTEIN TABLETS.

(MESSRS. PARKE, DAVIS, AND CO., BEAK-STREET, REGENT-STREET, LONDON, W.)

CERTAIN of these tablets contain 2½ grains of desiccated anterior lobe of the pituitary body, and others 3 grains of the posterior lobe (infundibular portion). The physiological action of the two lobes being different, it would seem correct to use the tablets independently. The anterior lobe extract has been used in delayed physical and mental development in children of a neurotic tendency, and amongst other maladies, in suppressed menstruation. The posterior lobe extract administered hypodermically or intravenously has been used with most favourable results in uterine inertia and uterine and pulmonary hæmorrhage. Orally its administration has been tried in acromegaly, paralysis agitans, and in certain skin diseases. It is reported that there is no increase in blood pressure when administered by the mouth, though that is the case when it is given hypodermically. The parathyroid tablets contain an equivalent of ⅗ grain of fresh glandular tissue. We have also received specimens respectively of cholera vaccine and a mixed vaccine for coliform infections, both of which are prepared in the vaccine laboratory of St. Mary's Hospital under the direction of Sir Almroth E. Wright. Lastly, we have examined specimens of nucleo-protein compound tablets which present an excellent formula. Each tablet contains 1 grain of calcium glycerophosphate, ½ grain of lecithin, and ¼ grain of nuclein. We had no difficulty in extracting and recognising lecithin. This formula is useful in the treatment of nervous exhaustion and nutritive disorders founded on neuroses.

PROTARGEN.

(MELLIN'S PHARMACY, 48, REGENT-STREET, PICCADILLY CIRCUS, LONDON, W.)

Protargen is an effective substitute for similar silver compounds of foreign origin. It is a light chocolate-coloured powder readily soluble in water. It is a true organic combination of silver in which the silver behaves chemically different from that present in the ordinary metallic salts. It is compatible, for example, with sodium chloride and albumin. It possesses the therapeutic activity of colloid preparations and readily penetrates the mucous membranes. Its use is suggested in gynæcological, ophthalmological, and urological practice.

THE ALLENBURYS CONCENTRATED FOOD PRODUCTS.

(MESSRS. ALLEN AND HANBURYS, LIMITED, 37, LOMBARD STREET, LONDON, E.C.)

Recent additions to the list of concentrated food products now made by this firm are: (1) diet tablets; (2) nutrient lozenges; and (3) meat soup squares. They are all easily portable foods and convenient for the soldier or the sailor or the traveller. The diet tablets are made up of milk solids with wheat and chocolate. They contain, therefore, all classes of food—proteins, fat, and starches. We found that the amount of protein was just 13 per cent. They are obviously useful for tiding over an emergency when substantial diet is not available. The nutrient lozenges consist partly of milk products with wheat to which are added beef extractives. In this case we found that the total proteins amounted to 25·61 per cent. The addition of beef extractives gives them an appetising flavour. These also serve a very useful purpose as an emergency food. The meat soup squares contained 41·63 per cent. of protein. Though not to any large extent soluble, these squares enable a very palatable soup to be made. The presence of meat fibre was confirmed by microscopic examination. These preparations, of course, find a very useful place in times of military campaign.

GRANSALO FOOD.

(MESSRS. S. HENDERSON AND SONS, LIMITED, SLATEFORD-ROAD, EDINBURGH.)

This granular preparation contains all classes of food substance—fat, carbohydrate, nitrogenous materials, and mineral salts. The proteins are derived for the most part from eggs and the carbohydrates from flour. The complete analysis of the preparation gave us the following results: Moisture, 7·80 per cent.; mineral matter, 0·90 per cent.; proteins, 15·43 per cent.; fat, 8·44 per cent.; total sugars, including milk and cane sugar, 34·24 per cent.; and starch, 33·19 per cent. The food in the course of its preparation is cooked, and may be used simply mixed with hot water, milk, or cream without any further treatment. The fat extracted proved to contain lecithin. It is a digestible and nutritious food and attractive in flavour.

UNGUEMOL.

(MESSRS. JOHN BELL, HILLS, AND LUCAS, LIMITED, TOWER BRIDGE-ROAD, LONDON, S.E.)

According to our examination this is a combination of substances which are antagonistic to the activities of vermin. It is free from any harmful ingredient or irritant, while it contains no corrosive or other agent which would spoil clothing. It is a fine light yellow powder and is contained in a canister with perforated top, a lever lid preventing loss of material when the tin is not in use. It contains, amongst other things, a bland oil, sulphur and naphthaline in a fine silica basis. It is intended especially for the eradication of lice on the persons of soldiers in the field.

TUBES OF TURTLE CUP.

(TURTLE CUP, LIMITED, 27, ADDINGTON-SQUARE, CAMBERWELL, LONDON, S.E.)

The idea of packing "turtle cup" in collapsible tubes is an excellent one. The tubes are very convenient in practice, and supply a portable, nourishing, and sustaining soup. The turtle gives the "cup" an attractive flavour, and an appetising soup may easily be prepared in this way. A spoonful or so placed in hot water yields all that is required. Turtle cup has been much appreciated by invalid soldiers and by patients who have little or no appetite for ordinary food. It contains something more than mere stimulating principles; it is a rapid and cheering nutrient.

DONATIONS AND BEQUESTS.—By the will of the late Mr. Thomas Groom Barker, of Eccles and Manchester, the testator left £600 to the Manchester Infirmary; £400 each to the St. Mary's Hospital, Manchester, and the Victoria University; £150 to the Royal School for the Deaf and Dumb, Old Trafford; and £150 to the Cheetham Hospital.—King Edward Hospital, Cardiff, has received a gift of 2000 guineas from Alderman J. H. Mathias, of Porth, Rhondda, for the purpose of endowing two memorial beds.

THE LANCET.

LONDON: SATURDAY, JUNE 5, 1915.

The War and the Supply of Medical Officers.

THE forty-first instalment of the *Times* History of the War, which appeared on Tuesday last, deals with British medical service in the war and takes an all-round look at the medical work which has been done in the field and at home. It does not pretend to be more than a very limited survey, but under the different activities and institutions selected for notice reference is made to most of those subdivisions of an enormous subject which are of essential importance. The position of the Army Medical Service at the time of the outbreak of the war is fairly stated. There is no doubt that we went into the war with a medical service good in personnel, but lacking many things in respect of which urgent demands were soon forthcoming. The moment it was clear that we were to take part as a nation in a vast European land war every member of the medical profession with the slightest experience foresaw that around the Army Medical and Army Medical Territorial Services there would have to be grouped much voluntary assistance. From the beginning of the war that assistance came in freely, and no doubt would have been offered more generally if exact knowledge had been provided as to the needs of the War Office. In the absence of this knowledge it seemed to many civilian medical men that their services were not required, an impression that was confirmed in some places by the rejection of offers of adherence. At first the transformation of various and numerous civilian buildings into war hospitals, some of which are mentioned in the *Times* History of the War, and many of which have been described in our columns, seemed unnecessary, particularly to those who were unable to imagine the developments in store. Everywhere we heard of schools being transformed into hospitals, of buildings being modified for Red Cross or St. John purposes, of country houses being handed over as hospitals and sanatoriums; and while the extent of the land war had not developed only a few people were able to read the signs of the times and to realise that the preparations which had been made would quite soon require to be strongly supplemented. But the various stages of the struggle during the past ten months have enabled us to envisage the situation, and we know that in the grim contest ahead, where all our national agencies and energies must be used with the utmost freedom, the medical profession will be further and further called upon.

Our military authorities think that it is absolutely necessary that we should have in training further large numbers of soldiers to take the place of the heavy depletions which are expected in the future, and of which the casualty lists have given us most dismal proofs in the recent past. More men mean more supplies, more camps, more barracks, more sanitation, and, implicitly, more medical officers, and already these officers have experienced considerable losses. At the summer session of the General Medical Council, which was opened on Tuesday last, the President, Sir DONALD MACALISTER, in a presidential address which we publish elsewhere in full, stated that the call for qualified physicians and surgeons to take up duty with the forces had become more and more insistent with the growth of the new armies, and added that our professional reserves, at no time large, had been drawn upon to the full—unless, we presume, some practical methods of readjustment can be devised. We know that the number of medical men already with the colours is very large, but even if the number remaining behind is in some directions barely adequate to our civil needs the further demands must be met. We are a nation at war. The needs of the army and navy are absolutely paramount. The places of those removed from their civilian work must be supplied by falling back upon every medical man who is unemployed; and those who feel that they are to some extent superfluous in their existing positions, and that they would be able to do more in other directions, must be brought in to civilian work if unable to serve with the forces for any reason. By arrangement of our scientific and administrative labour so that all suspicion of overlapping is done away with, there should be some gain of service; and, in the last event, the dropping of certain developments of public medicine, which though most valuable for the well-being of the country at peace, can for the time being be considered as accessories to the social scheme in time of war, and not as vital necessities, can be effected. No doubt in this way, by a rigid economy of the medical personnel of the country, coupled with some sorting up of that personnel, further civilian medical men can be found for the navy and army; and simultaneously it may be expected that the War Office will turn attention to the work that is being done by those who have already accepted commissions or who are doing part-time service with the forces, and will make sure that no waste is taking place there. If among these officers there is any systematic extravagance in numbers, if many are available for long periods where only few are wanted, this should be rectified at once. If many are doing clerical work whose places could be taken under proper supervision by civilians having no other than a business equipment, we feel that substitutes could be found among laymen who should be as unfitted by various disabilities for actual fighting as they are by lack of qualifications for giving medical help. It is possible that the supply of medical men already with the colours could be made to go further. The matter is one that has throughout engaged the attention of the War Office, and, of course, the members of a service can be manipulated to numerical advantage in a way that a heterogeneous mass of civilians, having nothing but their professional rank in common, cannot be.

We are foreshadowing what would come very near to mobilisation of the whole of the medical profession, and it may be that both individual justice to the medical officer and great advantage to our army and navy would follow if some such course were taken quickly. But it is unfortunate that this unprecedented demand upon our profession should find us with our ranks abnormally thin. At the end of 1914 there were over 1000 fewer medical students actually attendant on courses of study than in 1913. The recall to the schools of senior students who had volunteered for active service will arrest wastage of our numbers caused by the outbreak of war, and will enable the students in their fifth year of study to qualify in due time. But Sir Donald MacAlister has warned the General Medical Council that for several years to come a falling off in the number of qualified men must be expected. On the other hand, the possibility of complete medical reciprocity with Canada is at hand, and when the Medical Act of 1886 applies to the Dominion of Canada as it does already to the Commonwealth of Australia the evils of shortage will be counteracted. The British Medical Association, through a war emergency committee, which has recently been formed, is proposing to obtain a census of doctors as a first step towards judging what further help the medical profession can give, and has issued a form inviting medical men in the metropolitan district to state if they are willing to go on active service, or if they will undertake whole-time service at home or part-time service at home. We need hardly say that such voluntary registration, if it could be made effective, would be preferable in many ways to what is usually understood by mobilisation, for this in the case of a profession like ours presents an enormous amount of difficulty and would inevitably lead to many hardships. But in making a voluntary register this fact remains—the responsibility is placed upon each individual to make up his mind as to the seriousness of the situation, and the different conceptions on this point lead to unfair results.

Sanitary Scavenging.

The Public Health Department of the Local Government Board have most opportunely published a Return as to scavenging in urban districts in England and Wales which has been compiled from the schedules furnished by the authorities of those districts at the beginning of 1914. Ostensibly the inquiry was undertaken with the view of precaution before the onset of hot weather and had no reference to the war, but the heavy imposition placed upon the efficiency of our sanitary system by refugees and by the great number of troops in every town and village in the country has added a special value and importance to the findings. For, as is pointed out in a circular addressed to medical officers and the administrative bodies concerned, it is especially desirable at the present time, considering this congested state of affairs, and also when there are peculiar dangers arising from the spread of infectious diseases, that our sanitary authorities should do all in their power to prevent the retention of accumulations of refuse in the neighbourhood of dwellings and generally to maintain an efficient service for dealing with house refuse.

The Return should materially help domestic sanitation, for the information and advisory measures which it contains will be valuable in many directions, while in an appendix are given the arrangements at present in force for the storage, collection, and disposal of refuse in each urban district. In a preliminary memorandum the directions in which defective arrangements may prejudice public health are indicated, and how these arrangements may be improved is a further subject of consideration. The Board invite health authorities to deliberate whether in regard to their district certain elementary, though effective, principles are followed. The use of the sanitary bin in connexion with all new houses and buildings is enjoined, and especially the covered model, and it is suggested that in the populated parts of a district the scavenging should be undertaken by the authorities' own staff, who should remove all refuse in properly covered carts at least once a week, especially during hot weather. In places where no destructor is available the removal of refuse should be carried out with every precaution to prevent its causing nuisance and danger to health, and if tips are used these should be as remote as possible from dwellings and the material covered with earth and the tip fenced in. All these are quite simple suggestions, and they should be carefully followed throughout the land. Their application will go a long way towards preserving a clean bill of health during a period in which the beginning and continuation of infectious disease are alike favoured by summer conditions.

It will be readily recognised that as the efficiency of scavenging is increased so will danger from flies diminish, since it is well established that ashpits and refuse depositories are their favourite breeding places. From an ideal point of view house refuse should not be allowed to accumulate at all, and as the art of domestic architecture develops we can imagine that for every household there will be its own destructor. This is not yet practicable, although to some extent such a position is realised when as much as possible of the refuse is destroyed in the kitchen fire. With, however, the increasing use of gas and electricity for cooking purposes the domestic facilities for burning refuse will get smaller and smaller. On grounds of public health fire is the best scavenger of all, but except in large towns the destructor is generally too expensive a proposition. We still await a destructor which by automatically effecting economies can be brought into service in every community, whether large or small. At present it is only the luxury of large and rich districts, and often then it is a source of nuisance.

Annotations.

"Ne quid nimis."

INDUSTRIAL ACCIDENTS IN AMERICA.

IN the United States of America human life is cheap and industrial accidents frequent. An estimate by Mr. T. J. Riley in the Bulletin of the Department of Health, City of New York, places the number of deaths by such accidents at nearly 35,000 per annum. It is calculated that the total number of both fatal and non-fatal industrial accidents must be about 700,000 a year. On the average, 9 railway employees are killed by accident every day in the United States, and 1 is injured every 11 minutes. Out of every 200 coal-mine employees, 1 is killed by accident yearly. These figures refer to occupied males above 15 years of age, and do not include the women workers; it must be noted that four-fifths of the men thus injured are 40 years of age or under, so that the economic waste due to these accidents is extremely large, the victims being struck down in the prime of life. Among the transport workers, it is said, fatal accidents are about three and a half times as common in the United States as they are in Great Britain. More than half the fatal and non-fatal accidents are due to unguarded or inadequately guarded machinery in motion; the remainder are caused by falling bodies, collapsing buildings, explosives, hot liquids, acids, and steam. These facts indicate the nature of the precautions that should be taken to reduce the excessive number of accidents. Moving machinery must be guarded, lifts must be made fool-proof, automatic mechanisms must take the place of human beings or human interference, and the inspection of scaffoldings, buildings in course of erection, lifts, and the like, must be made effective. In America, it seems, it still costs less to kill a man by accident than to protect him against injury. Mr. Riley advocates the wider recognition of the principle expressed in the terms "employers' liability" or "compensation"; at the present time charitable help still plays an unduly large part in making good the social and economic losses caused by industrial accidents. He points out that there is much room for the improvement of hygiene in the pit, shop, or factory; improved hygiene means lessened incidence of disease, particularly occupational disease. Fatigue, again, whether mental or physical, predisposes to the occurrence of accidents, so that unduly long hours of labour should not be allowed. The worker is to be insured for his own benefit against both accident and disease. Who is to pay for the insurance? In the case of accident, Mr. Riley believes, the industry should bear the whole cost. In the case of illness the conditions are not the same; the work and the conditions of the work are responsible only in part for the sickness, and so the cost of insurance against occupational disease should be borne in part by the industry, in part by the worker. Charitable help for these victims of accident or disease is still requisite, and should be given in adequate amount and intelligently. But first and foremost steps should be taken to bring down the number of accidents and to lessen the incidence of occupational disease; both are altogether too high in America.

THE MEMORIAL TO MADAME DEPAGE.

THE following subscriptions have been received towards a memorial to Madame Depage, the wife of Professor Depage, who was drowned in the wreck of the *Lusitania*, when returning from the United States, where she had gone to collect funds for the Depage hospital at La Panne:—

	£	s.	d.
Sir T. Lauder Brunton, Bart., F.R.S.	10	10	0
Mr. D'Arcy Power	5	5	0
Capt. W. J. Greer, R.A.M.C. (T.)	3	3	0
Professor Sinclair White	2	2	0
Mr. Robert Jones...	2	2	0
Lieut.-Col. A. W. Sheen, R.A.M.C.(T.)	1	1	0
Mrs. D'Arcy Power	1	1	0
Mr. W. D. Spanton	0	10	6

All who wish to contribute are requested to send their subscriptions to Mr. D'Arcy Power, 10A, Chandos-street, Cavendish-square, W.

MUMPS.

IN a critical review of this common infectious disease in the *Quarterly Journal of Medicine* (1915, vol. viii., p. 255) Dr. Anthony Feiling brings forward certain observations not very generally known. As regards its causation some valuable and suggestive experiments have been made by Nicolle and Conseille. They were quite unable to find any micro-organisms in the fluid obtained by aspiration of the parotid glands of patients with mumps. But with the fluid so obtained they injected the parotid glands of three monkeys. All three developed, after an incubation period varying from 16 to 26 days, a febrile illness lasting two to seven days, and one suffered from a definite swelling of the left parotid gland. The blood in one animal was noted to show a mononuclear leucocytosis. The same monkey which developed this attack of apparent mumps was subsequently reinoculated, but failed to develop any illness, suggesting that immunity had been conferred by the first inoculation. Dr. M. H. Gordon induced in monkeys, in four out of the ten used, symptoms of severe meningeal irritation and death, following inoculation in sterile saline of a filtrate of saliva from patients suffering from mumps. These experiments suggest that mumps is due to a filterable virus comparable to that of poliomyelitis, small-pox, and typhus fever.[1] The blood changes in mumps are important; there is a relative and absolute increase of the lymphocytes; this is present on the first day of the disease, and persists for 14 days. This is of value for diagnosis. Besides the complication of orchitis, present in 20 to 30 per cent. of cases and coming on during the height of the disease, pancreatitis may occur. Nervous complications also are fairly frequent. Mumps, then, whilst usually not serious, the mortality being only 3 per 1,000,000, may present startling clinical symptoms in some cases, and these offer confirmatory evidence of the generalised infection suggested by the animal experiments.

---

[1] On a Fatal Illness in Children associated with Acute Interstitial Parotitis, M. H. Gordon, THE LANCET, August 2nd, 1913, p. 275.

REMOVAL OF A SHELL FRAGMENT FROM THE CAVITY OF THE RIGHT VENTRICLE.

AT a meeting of the Académie de Médecine of Paris on May 4th M. Beaussenat reported a most extraordinary case—the survival of a man with his right ventricle pierced by a fragment of shell which lay free in its cavity, and its successful removal by operation. Wounds of the heart have often been successfully sutured, but removal of a foreign body from one of the cavities does not appear to have been even attempted. A sergeant of the 91st Infantry Regiment was wounded at Saint-Hubert, in Argonne, on Oct. 1st, 1914, by a hand grenade which exploded at his feet. He was hit by three projectiles—in the left deltoid region, in the front of the right thigh, and in the chest. The last projectile entered at a point a finger-breadth below and to the left of the point of the xiphoid cartilage. Severe præcordial pain and dyspnœa followed. There were hæmoptysis and abundant hæmorrhage from the epigastric wound, which was arrested by applying a dressing. After remaining 24 hours at a dressing station he was removed to hospital. The hæmoptysis was arrested on the fifth day. A radioscopic examination of the chest was made and the report was: "Shrapnel bullet entirely free on the diaphragm." He was never free from painful dyspnœa on effort and præcordial anguish, especially at night. He was taken to Nantes, where, after several radiographic and radioscopic examinations, the diagnosis was: "Fragment of a ball implanted in the pericardium and following all the movements of the heart." Inspector-General Delorme proposed an operation, which the patient declined. He left hospital on Jan. 26th, 1915, on seven days' leave, in the course of which he presented himself for medical examination at Paris. He complained of a persistent sensation of anguish which had much increased since he had left hospital. He was admitted to Auxiliary Hospital 147 on Feb. 4th. The face was pale and a little anxious. The breathing was short and became very rapid when he stood up, walked, or even spoke. He was careful to walk quietly, to speak slowly, and not to make brusque movements. He was more uncomfortable in the horizontal than in the vertical position, and his nights were particularly bad. He had a tendency to hold his hand over his heart, which was simply excitable without any murmur or other sign, except a kind of thrill at the apex. A radioscopic examination was made by Dr. Jaugeas, who found "a small fragment of a projectile with regular movements of little amplitude, synchronous with the heart beats and not influenced by suspension of respiratory movements, manifestly intrapericardiac." On Feb. 17th Dr. Beaussenat made a transverse incision 13 centimetres long over the left fifth rib, which he resected with its cartilage for a distance of 8 centimetres. He pushed back the pleura and exposed and incised the pericardium; it contained liquid, not tinted, but more abundant than normal. Thinking that the projectile might be arrested in the myocardium, he explored the latter systematically. On palpation of the right ventricle he found that it contained a hard movable body. The heart was luxated out of the pericardium and so maintained by two silk loops passed into the wall of the right ventricle. The projectile was brought in contact with the external border of the ventricle near the apex and held there between the left thumb and fingers. While an assistant exercised traction on the silk threads, so as to strain the ventricular wall, M. Beaussenat carefully incised it between them. A gush of dark blood occurred and was instantly arrested by pressure with the index finger, over which during the diastole was passed a forceps and the projectile was seized and removed. It was a metallic splinter of irregular outline 1½ centimetres long and weighing 1½ grammes. The heart wound was sutured with silk and the pericardial and superficial wounds were closed. For three days there was intense dyspnœa and the pulse was feeble and irregular. A marked rhythm "à trois temps" was heard. Recovery, though interrupted by three attacks of pulmonary embolism, was complete on March 17th. Examination in April with the electrocardioscope by Dr. Josué showed only predominance of the left ventricle.

A NEW TEST FOR URINARY SUGAR.

THE difficulties associated with the performance of the ordinary tests for sugar in the urine, of which Fehling's is by far the most commonly employed, are well known, so that the invention of a new diagnostic reagent is a matter of considerable clinical importance. In the *Biochemical Journal* for March Dr. William Cramer describes a method of employing the reduction of a weakly alkaline solution of mercuric oxide to metallic mercury in the presence of suitable sugars, which he considers to have special advantages as a test. The reagent is prepared by dissolving 0·4 gr. of mercuric oxide, red or yellow, with 6 gr. of potassium iodide in 100 c.c. of water, and adjusting the alkalinity of the solution so that 10 c.c. are neutralised to phenol-phthalein by 2·5 c.c. of decinormal acid. The resulting solution is colourless in the cold and turns slightly yellow on boiling. To test for sugar in urine 3 c.c. of the reagent are heated to boiling; then 0·3 c.c. of urine is added and the mixture again boiled. On removing the test-tube from the flame, the mixture darkens if sugar be present, and a deposit of black metallic mercury gradually settles to the bottom. Not only glucose, but lactose, maltose, xylose, and arabinose give the reaction, while cane sugar does not. The sensitiveness of the test fluid can be varied by increasing or diminishing its degree of alkalinity, and the point fixed, as stated above, corresponds to a degree which gives a faint reaction with normal urine, which is known to contain about 0·1 per cent. of sugar. If the reagent is made more alkaline and thus more sensitive, it may give a precipitate with creatinin and other organic substances. Dr. Cramer finds that the "2·5 standard" solution gives a definite reaction with small amounts of sugar in the urine, which only produce doubtful results when tested with Fehling's fluid. He suggests as an indication of the degree of the reaction the possibility of reading print through the solution when boiled in an ordinary test-tube 30 seconds after this is removed from the flame, a few drops of acetic acid being first added to remove any possible turbidity due to phosphates. Small quantities of sugar can thus be recognised and roughly estimated. Ammoniacal urine must not be used for the mercuric test any more than in performing Fehling's reaction. Possibly for ordinary clinical testing the "2·0 standard" solution, which gives no reaction with normal urine, may seem preferable, but Dr. Cramer considers that there is no reason to ignore the minute amount of sugar normally present, when small variations from this percentage can be readily demonstrated.

THE WHITE MAN'S BURDEN IN WEST AFRICA.

THE gravity of the white man's burden in the tropics is now generally recognised. In few places has this burden in the past been greater than in West Africa, and, indeed, it is not so long ago that one of our British colonies in that region was commonly spoken of as "the white man's grave." In recent years continued and strenuous efforts have been made to remedy the conditions which were deleterious to the health of Europeans and natives in West Africa. These efforts have already given encouraging results by reducing both the sickness and the mortality rates, especially among the officials serving in these colonies. In this connexion Dr. A. E. Horn, of the West African Medical Staff, in a paper which he contributed to THE LANCET of May 18th, 1912, drew attention to the improvement which had then taken place and pointed out that credit for the application of the recognised principles of tropical medicine and hygiene was due to the Colonial Office and also to local administrations. These latter, he showed, had consistently authorised and approved of expenditure on sanitary works such as the drainage of marshes, the carrying out of anti-mosquito campaigns, the demolition and reconstruction of native towns and stations, along with the provision and proper control of wholesome water-supplies, and the like, all of which were calculated to improve the conditions of living, not only for Europeans but also for the African natives themselves, and assist, directly or indirectly, in the economic development of the colony. We have received a copy of the report for 1914,[1] just issued, on the vital statistics of non-native officials in the four West African colonies of the Gambia, Sierra Leone, the Gold Coast, and Nigeria, which together employ a white staff of 2641. Owing to the great European war and the resulting military operations in German Togoland and the Cameroons, the burden placed upon the officials of these British colonies was much heavier than usual. Notwithstanding this, the statistics now published present certain satisfactory features. In the year 1905 the death-rate from all causes in the non-native officials was 28·1 per 1000; but in 1913 the rate had declined to 11·8. The year 1914 was exceptional, and it therefore hardly lends itself for comparison with previous years. A large number of officials were released by the colonial Governments for service with the colours at home; others resigned or otherwise determined their appointments for a similar purpose. Moreover, besides the majority of the West African Frontier Force, a great many civil officers were attached to the forces operating in Togoland and the Cameroons, where, apart from the direct casualties in the field, they were naturally exposed in the circumstances to greater risks of disease and other dangers than if they had remained at their posts in their respective colonies. Further, the depletion of the normal staff threw extra work upon those who were left, and also necessitated the retention of many officers in West Africa for periods considerably in excess of the usual length of tour, with the result that the health of some of them suffered and a proportionately higher number of invalidings ensued. Reckoning all the deaths that occurred among the European officials during 1914, the mortality rate was 19·3 per 1000; but if the casualties, 18 in number, in the military operations in Togoland and the Cameroons are deducted, as also 3 other deaths directly due to these operations, the death-rate for 1914 is reduced to 11·6, which is actually just under that of the previous year. The invaliding rate, in spite of the adverse conditions above indicated, was 36·4 per 1000, as compared with 42·6 in 1913. It appears, then, that notwithstanding the exceptional circumstances of 1914, these West African colonies have continued to maintain the progress which had been previously observed. There are, therefore, reasonable ground for believing that the white man's burden in West Africa is being sensibly lightened year by year by the application of the principles of modern science.

VENEREAL DISEASE IN NORWAY.

VENEREAL disease is notifiable in Norway, and during 1914 just over 2000 cases of gonorrhœa and syphilis were notified in its capital, Christiania, which has a population of about a quarter of a million inhabitants.[1] The notification is made by medical practitioners and hospitals, and over 83 per cent. of those notified were males; over a third of all the notifications were made in the month of December, June being the month with the next largest number of notifications. There were 556 cases of syphilis, and it is noted that the infection was extragenital in 20 of these, 6 males and 14 females, the tonsils or lips being the seat of the infection in 11. There were 38 new cases of congenital syphilis, and it is recorded that a special hospital for the treatment of this condition, with 20 beds, was opened in 1914 by the Oddfellows' Lodge at Christiania. It appears that in only 78 cases was the infection acquired in some other town, a low proportion in a harbour visited by so many seamen as Christiania. In 78 instances evidence as to the source of infection was given sufficiently definite to cause special inquiry to be made, and in 60 of these the inquiry gave a successful result. The law allows punishment up to three years of imprisonment to be given to any person who exposes another to venereal infection while knowing or suspecting that he or she has venereal disease himself or herself; 9 men and 18 women were prosecuted under this law, and 2 of the men and 7 of the women were convicted.

MEDICAL DEFENCE.

THE annual meeting of the London and Counties Medical Protection Society was held at 32, Craven-street, Strand, W.C., on May 26th. Dr. G. A. Heron, the president, was in the chair. The report of the council, which was submitted to the meeting and unanimously agreed to, showed a satisfactory record of work for the year. During 1914 the number of applications from members asking for advice and assistance was 621, as compared with 608 during the year 1913 and 575 in 1912. The majority of cases were dealt with successfully without recourse to legal proceedings, and in cases where litigation was necessary the results were also satisfactory. The expenditure on legal action was somewhat heavy, but there was nevertheless a satisfactory increment of the surplus funds of the society at the end of the year. The report showed that 400 new members joined in 1914. Dr. Heron, in his address from the chair, spoke of the need for closer coöperation among medical men in regard to medical defence, and

West Africa: Vital Statistics of Non-Native Officials, Returns for 914, H.M. Stationery Office, price 1½*d*.

[1] Y. Ustvedt, Tidsskrift for den Norske Laegeforening, Kristiania, 1915.

alluded to a scheme for amalgamation between the London and Counties Medical Protection Society and the Medical Defence Union, which was considered as far back as 1893 without success. He alluded to the support given by THE LANCET then and later to the idea of a fusion between the two societies in terms which suggest the possibility that the idea may revive.

SCIENCE IN CATALONIA.

OVER the greater part of Spain the language spoken is Castilian, nowadays commonly known to us as Spanish. But not less Spanish are two other tongues equally derived from the vulgar Latin once used in Spain—namely, Portuguese-Galician, employed along the western border of the peninsula, and Catalan, spoken by some 3½ million Spaniards living along its eastern border and in the Balearic Islands. As a language Catalan came into existence in the ninth century, when it was brought into Spain from the south of France, Languedoc, by the returning Spaniards, who had been driven northwards out of their country by the Arab invasion in the second decade of the eighth century. Catalan literature, never very extensive in scope or large in quantity, was at its best in the fifteenth century, and after that period fell into decadence from desuetude; Castilian took the place of the Catalan tongue among the educated, and Catalan fell into the position of a *patois*. But about a hundred years ago a revival of the Catalan language and literature was essayed with no little success, and at the present time the effort is well maintained in both poetry and drama. A further example of the new vitality of Catalan takes the form of a "Biological Society" at Barcelona, which published its first year-book in 1914. During the year this society held eight sessions, at which the members read and discussed 30 papers on medical and pathological subjects exclusively, and one on a matter of palæontology. Seven of the papers deal with the electrocardiograph, and are illustrated with numerous electrocardiograms. J. Marimon discusses the question whether both myxœdema and exophthalmic goitre may not be two manifestations of the same disease, hypothyroidism. R. Carrasco details a number of blood-counts in patients with Basedow's disease, showing that in it there is a deviation to the right in Arneth's neutrophil scheme, together with an increase in the nuclear number. Ll. Sayé finds a similar deviation in the leucocytosis produced in both man and rabbits by artificial pneumothorax. He believes that the establishment of such a pneumothorax produces a mild aseptic inflammation in the collapsed lung, and that this accounts for the leucocytosis, which is polymorphonuclear in man, eosinophil in the rabbit. J. Peyrí gives a contribution to the study of McDonagh's leucocytozoon syphilidis, finding himself not in complete accord with some of McDonagh's interpretations of the phenomena observed. Of other papers in the year-book three are written in Spanish, all the rest are in Catalan. The Biological Society of Barcelona is to be congratulated on its scientific activity.

AMONG the new Knights there are two well-known medical men who have earned the honour by scientific and administrative work in medicine. We congratulate Sir James Mackenzie, the distinguished worker in cardiac problems, and Sir Frederick Needham, the well-known expert in lunacy, upon the official recognition of their excellent work.

SIX MONTHS WITH THE BEARER DIVISION OF A FIELD AMBULANCE AT THE FRONT.

BY S. J. A. H. WALSHE, D.S.O., M.B., CH.B.EDIN.,
CAPTAIN, R.A.M.C.

HAVING been during the first six months of the present war in charge of the Bearer Division of a Field Ambulance at the front, I am tempted to record some of my experiences in the hope that they may be at least interesting, if not perhaps useful, to officers who at a later date may have to undertake similar duty.

In this campaign, owing to modern gun fire, it has generally been found quite impossible for the Bearer Division whilst remaining with its Tent Division to go forward, collect the wounded during or after an engagement, and return with the casualties collected to headquarters that night. The Tent Division must of necessity be some miles behind the firing line to be totally outside the zone of fire. To perform its duties properly the Bearer Division cannot possibly remain so far back, owing to the distance and the time which would be lost in coming up. It must almost invariably be in front of our own guns and take up its position from, say, 500 yards to two miles behind the front trenches. Whilst the particular area held by the infantry brigade or units from which wounded are to be collected will be pointed out to one, the selection of the actual site to be occupied by the Bearer Division may be left to the officer in charge, in which place, as a matter of course, an advanced dressing station will be established.

Selection of Site of Advanced Dressing Station.

The selection of this site requires some consideration. One may make it a rule that a battery in action, a bridge over a canal or river, or a chateau (marked as such on the map) are best avoided, as they are most likely to attract the enemy's fire. Neither should the vicinity of a railway station be occupied owing to its gun range being known. Billeting areas of troops are generally observed by hostile aircraft, and for that reason should be avoided.

The most elaborate and possibly the best laid-out advanced dressing station which I have seen was in a railway station. Every available room and all the offices were commandeered for the purpose. No detail appeared to have been overlooked. There was quite a good operating-room fitted up, also a room where patients were to be kept prior to operation, as well as one to which they were to be transferred when operated on. This dressing station might well have been taken as a model, which, indeed, it would have been had it not from its environment been a still better model of a death trap. Unfortunately, it was in a railway station, which in itself is a danger zone, a canal bridge previously shelled by the Germans was not 40 yards away, the adjoining village was entirely occupied by troops, an armoured train came up daily to the station to fire, and as if to complete the picture there were two railway trucks of high explosive shells not 20 yards from the dressing station itself. I have given this instance to demonstrate that the site of a dressing station is of infinitely greater importance than the particular type of house used for the purpose.

When ordered to form an advanced dressing station it is desirable to find some suitable house easily accessible from the road, with good accommodation for patients and the personnel, and near where horses can be stabled, but if possible at least 400 yards away from a battery, or a bridge, or chateau, and as near to the front trenches as the brigade commander thinks desirable. If the sanitary condition of the place and its water-supply are not all that could be desired, one has got to make the best of what one finds.

It is essential that ambulance wagons should be hidden when not in use by covering them with branches of trees, as in the present campaign the Red Cross painted on the wagons has not secured their protection from shell fire. It is unfortunate, but none the less a fact, that ambulance wagons have been shelled by the enemy from a distance at which he could not possibly have mistaken them for any other transport. I have had the position of my dressing station marked by hostile aircraft having detected the ambulance wagons (a large red cross was painted on the top of them) and was severely shelled almost immediately afterwards. It is a wise precaution to have dug-outs or trenches made quite close, which can be utilised when necessary, and it will occur occasionally that a Bearer Division will be compelled to occupy dug-outs entirely.

Collection of Wounded.

When the number of casualties is small the number of wounded are usually collected by the regimental stretcher bearers and carried to the regimental aid posts, from which places it becomes the duty of the Bearer Division to evacuate them to the Tent Division, or possibly to some clearing station. During and after severe engagements the number of casualties is necessarily large, and the work of collecting the wounded becomes too great for the regimental stretcher bearers. Then the Bearer Division must assist them to get the wounded back from the trenches. For this and other reasons it has been found necessary in the present campaign to place the Bearer Division in communication with the headquarters of the infantry brigade, from which it has to evacuate wounded. Such communication is a matter of much importance, and on the way in which it is maintained will, to a large extent, depend the rapidity with which casualties are collected and evacuated. It may be effected in the following ways. 1. By means of a telephone wire laid from headquarters of the brigade to the advanced dressing station. 2. By a cycle orderly. In either of the foregoing methods the entire evacuation is carried out through the medium of the brigade staff, who send direct to the officer in charge of the Bearer Division information as to the number and disposition of casualties and the time when they consider it best to collect and evacuate them. 3. By means of a "liaison" officer. In this method a mounted officer of the Bearer Division with a cycle orderly is told off to remain with and accompany Brigade Headquarters. His duty is "to keep constant touch with the Officer Commanding the Bearer Division by means of his cycle orderly. He must observe where casualties occur or are collected, their numbers, &c. He must note the ground passed over by the brigade, and must lead the Officer Commanding the Bearer Division to the position of the wounded when suitable occasion occurs." In carrying out these orders the liaison officer must be constantly in touch with the regimental medical officers, and so become acquainted if the casualties are too numerous to be collected by the regimental stretcher bearers, and, if so, he reports how many stretcher squads from the Bearer Division each battalion or other unit will require. He also becomes acquainted with the cases which are most seriously wounded (and these require to be evacuated first), how many cases can sit up when pressed for accommodation in wagons, and, further, the most suitable and safest place for a wagon rendezvous.

All these facts communicated at once to the officer in charge of the Bearer Division bring about an extraordinary saving of time in the evacuation of casualties, when time is often of the utmost importance to the lives of the more seriously wounded. This time-saving, to my mind, makes the liaison officer method infinitely the best of any system with which I am acquainted for the collection and evacuation of wounded.

No matter how anxious a brigade staff may be to give information of the type just mentioned, they cannot do so; it is not their work. It is essentially the work of a medical officer, and if left to a layman (in the medical sense of the word) when casualties are numerous unfortunate mistakes are not unlikely to occur.

I, in compliance with instructions, adopted this method during the entire period of the heavy fighting around Ypres in October and November, 1914, when casualties were numerous. I was fortunate in possessing an efficient and capable liaison officer, whose prompt and accurate information enabled me on many occasions to save hours in the collection and evacuation of wounded. The brigade staff readily expressed their approval of the method. It relieved them of all anxiety about the wounded, and thus gave them more time for matters of even still greater import.

The objection most often raised to this method is that it deprives the Bearer Division of the services of one officer. This to a certain extent is the case, but his services are being utilised instead to the best possible advantage where casualties are most likely to occur. I am not at all at one with those who hold that several officers are required with a Bearer Division; indeed, for the greater part of the time around Ypres, during the most severe engagements, the only officer I had to assist me was my liaison officer, and I am quite satisfied that whilst so employed he gave me an amount of assistance which far excelled any work that he could have done for me had he remained at my dressing station. At that time I also had a most reliable non-commissioned officer to assist me.

Transit of Wounded.

At the outbreak of the war the only means of transport for wounded which Field Ambulances possessed were two-horsed ambulance wagons, ten in number. These wagons went to the advanced dressing station with the Bearer Division. However, since last November motor wagons with practically the same holding capacity as the horse wagons have been in use at the front, and their advantages over the latter are obvious.

It is not possible that motor wagons will entirely replace the older horse wagons, and as far as my experience goes there are sound reasons why they should not do so. In the first place, a horse wagon can travel over old, ill-kept roads or over fields which would be quite impossible for a motor wagon to do. Secondly, even good roads in France and Belgium are usually exposed, and when at all near the firing line are not safe for any transport during the day; and at night head-lights may not be used. On this account motors are highly untrustworthy at night near the advanced trenches, and to add to their difficulty the roads would probably have several shell holes. Finally, where a large amount of transport passes to and fro at night the most careful chauffeurs or drivers will occasionally get their vehicles into a ditch, and it is a much easier matter to get a horse wagon out of a ditch than it is to get a motor.

A procedure which was found very useful at Ypres was to send the horse ambulance wagons up as near to the regimental aid posts as the conditions would allow, and bring the patients back—about two miles—to a place where they would be transferred to the motor wagons, which would take them to the appointed Tent Division several miles back.

Recently the Field Ambulances of the Second Division have been supplied with wheeled stretchers (the McCormack-Brook pattern). These have proved to be of the greatest use in saving both time and labour in getting casualties unable to walk from the regimental aid posts to the wagon rendezvous when the distance to be traversed is quite impossible for any ambulance wagon. The opinion about their utility is not unanimous, but the persons who dispute the point have not, one would imagine, ever acted as stretcher-bearer for 1500 to 3000 yards. If they had they would think otherwise.

I previously mentioned that the billeting site of a Bearer Division will, as a matter of course, be utilised as a dressing station. It is not suggested that the cases evacuated from the regimental aid posts should ever be taken in there; they are sent straight to the Tent Division. However, many slightly wounded cases who are able to walk will be directed to the advanced dressing station from the aid posts and trenches, but it will come in still more useful as a place to which the medical officer in charge of the brigade of artillery can send his casualties. And here it might be mentioned that during the first day or two of an engagement this medical officer may be quite at a loss to know where he can send his wounded, not being acquainted with the sites of the dressing stations.

The officer in charge of a Bearer Division would materially assist the brigade medical officer were he to send an orderly to the nearest battery and indicate to them for the information of their medical officer where his dressing station is situated.

Casualties must not be allowed to accumulate at the advanced dressing station owing to the danger of shell fire. It is well for the officer in charge to bear in mind that rapidity of evacuation should be his aim rather than medical or surgical treatment, which can be so much better carried out in the Tent Division or hospital to which cases may be evacuated.

A Point in Treatment.

There is one type of case which perhaps may be made an exception to the rule just mentioned. It is outside the scope of this article to touch on treatment. But when one has had on many occasions cases brought into a dressing station, which have bled profusely from a severe shell wound or are suffering from shock, one ventures to hope that an officer in charge of a Bearer Division will be supplied with the means of giving an intravenous saline injection. The patient's condition is usually such that it is only too obvious that nothing can save him except an injection of normal saline solution. I specially mention the intravenous method because a rectal injection would probably not be retained, or if it were, would not be absorbed sufficiently fast. Delay is also the objection to the subcutaneous or intramuscular method.

I am quite aware that this suggestion will be met with the objections that I am likely to cause an early and profuse reactionary hæmorrhage, which is exactly the condition to be avoided, that I cannot take proper aseptic precautions in the field, and that I may possibly bring on pulmonary œdema. Very well; if I am not prepared to take those risks and work on the principle that being forewarned is to a certain extent being forearmed, I default. I have seen more cases than one in which I had no doubt whatever that an intravenous injection of saline solution would have given more than a probability of saving life, and I am not the only person serving at the front who from experience holds the opinion.

Before closing I wish to make it clear that in this article I do not, under any circumstances, mean to address myself to officers of some years' standing who naturally have their own ideas as to how the Bearer Division of a Field Ambulance should be run, which ideas possibly differ from and are preferable to mine. I have written in the hope rather that my experiences, differing as they do in some respects from one's preconceived ideas, may be of some little use or interest to those officers who, not having of necessity had an extensive military training and not having had any previous experience of actual warfare, may find themselves in the near future coming to the front with the new armies and placed in charge of the Bearer Division of a Field Ambulance.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Early Treatment of Tetanus in Military Hospitals in Time of War.

Dr. Bacri has communicated an interesting paper to the Académie de Médecine, and has insisted on the great importance of early diagnosis of tetanus in wounded patients in the preliminary period of infection, while as yet the patient is not seriously poisoned and while serum injected at this period possesses really curative properties. The following is the method which he has used in his hospital, thanks to which he has had the satisfaction of discovering in time and curing two cases of tetanus which declared themselves in the wards. This method was inspired by the preconceived idea that every wounded patient who enters a military hospital is perhaps infected with tetanus. Every day, morning and evening, the patient should be made to open his mouth, the doctor taking note of the distance between the jaws, and finding out the state of tension which is more or less painful in the angle of the jaw. If in any doubt, he should explore the patellar reflex. The testing of the maxillæ and of the patellar reflex barely occupies a minute. The diagnosis arrived at, inject 40 c.c. of antitetanic serum every day for four consecutive days. In two cases the cure was assured on the fifth day after the first injection. The patellar reflex became normal on the eighth day. The cure was complete on the twentieth day. The systematic examination established that there exists immediately after the period of incubation, at the beginning of the period of invasion of tetanus, a period of treacherous abeyance during which three symptoms, that are easy to discover, point on the surface to the toxic impregnation of the maxillary axis; these are the lessening of the usual width of opening between the jaws; a painful contraction caused by a slight increase in the opening of them; and the very considerable increase of the patellar reflex. At this initial period of infection the antitetanic serum possesses a marvellous efficacy, and its action is by no means inferior as a specific to antidiphtheritic serum.

Preventive Treatment of Typhoidal Peritonitis.

In cases of typhoid fever during the war peritoneal complications are particularly frequent because of the unusually exhausting conditions to which the men are subjected during their evacuation and also because of the defects in their feeding during the same period. As peritonitis in suffering soldiers is almost always fatal, whether operated on or not, M. Courtellement considers it of paramount importance to attempt to prevent its development. In his opinion a suitable treatment, undertaken at an opportune time—that is to say, during the period which he calls pre-peritonitic—offers very excellent chances of success. According to M. Courtellement, three symptoms at this period reveal peritonitic reaction. These are the distension of the abdomen, vomiting, and abdominal pains. As a rule one symptom only, rarely two, indicates the existence of the preperitonitic period. Of the three symptoms the more frequent is the distension of the abdomen. This ought to be taken into account each time that it becomes marked. The vomiting as soon as it is repeated without a plausible cause, in the form of true vomiting or of regurgitations, constitutes a strong indication of peritonitic reaction. As to the pains of the preperitonitic period, they habitually present themselves in the form of intestinal colic; at other times affecting the whole abdomen or of one region, and are spontaneous or at times revealed or exacerbated by the ingestion of liquid. When the peritonitic condition characterised by one of these symptoms has been recognised a special treatment should be commenced without delay; this varies according to whether we are dealing with a slight or a severe case. In slight cases it is sufficient to prescribe immobility on the back. On the abdomen damp tepid compresses may be applied, entirely covering it, squeezed out to get rid of excessive liquid, or else an ice-bag may be used covered with flannel. No milk to be given. In serious cases the treatment requires the same immobility, of course, and prolonged applications of ice on the abdomen. Complete abstention from all drinks, either of the nature of milk or water. The patient is only allowed to suck little fragments of ice if he shows a tendency to vomit, and subcutaneous injections of saline solution, the dose to be one litre per day, 500 c.c. being injected in the morning and 500 c.c. at night. This treatment may be continued on an average three days.

May 31st

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Appreciation of Medical Services in the Persian Gulf.

THE Commander-in-Chief has received the following telegram from the General Officer commanding the force at Basra: "I have received from all quarters glowing accounts of the conduct of medical officers, assistant surgeons, sub-assistant surgeons, and the army bearer personnel of the Shaiba force and of the line of communications. In the action they displayed great bravery, while throughout the strenuous and unremitting labour of the last six days and nights their devotion to duty has evoked universal praise. Including those of the enemy, over 1100 wounded have been attended to and evacuated to the general hospital at the base under conditions of unusual difficulty and strain on the medical personnel, who have nobly done their duty."

Irrigation in the Central Provinces.

The Central Provinces are beginning to benefit from the irrigation works undertaken of late years. As Sir William Meyer said in his speech in introducing the annual financial statement, the Mahanadi Canal has begun to furnish water for irrigation, this being the first canal system constructed in those provinces. Good progress has also been made on the Waiganga canal and the Tendula reservoir. As in 1915-16 18 lakhs are to be spent on the Mahanadi project and nearly 10 lakhs on the other, the rate of construction will be fully maintained. A few years hence the Central Provinces will have quite a large area under irrigation from canals as distinct from that served by tanks, which hitherto have been the only means of conserving water for the land.

Mysore Sub-Assistant Surgeons.

The Mysore Government is contemplating the opening of a new branch for sub-assistant surgeons in its service. It is understood that a number of sub-assistant surgeons are to be specially trained every year in malarial field work and the causation and prevention of malaria.

Deaths from Snakes and Wild Animals in Assam.

The number of persons killed by wild animals and snakes in Assam during the year 1914 is reported to have been 126 and 150 respectively, as compared with 102 and 167 in the preceding year. Tigers were mainly responsible for the increase in the number of persons killed by wild animals, the number of casualties due to these animals being 49, as against 33 in the previous year.

Sanitation in Assam.

A Sanitary Commissioner has now been approved for Assam. The province has hitherto had only a Deputy Sanitary Commissioner.

Military Hospital Nurses.

The Government of India has sanctioned the engagement temporarily of additional fully trained nurses for duty in military hospitals in India. Applications should be addressed to the Director of Medical Services in India, Army Headquarters, Simla.

May 4th.

EUGENICS EDUCATION SOCIETY.—At an afternoon meeting, to be held at the Grafton Galleries, Grafton-street, W., to-day, Friday, June 4th, at 5.15 P.M., Professor Elliot Smith, M.D., F.R.S., will discuss the Influence of Racial Admixture in Egypt. Major Leonard Darwin will preside.

ANNUAL REPORT FOR 1913 OF THE REGISTRAR-GENERAL.

(*Concluded from p. 1149.*)

Analysis of Deaths in Institutions.

AN important addition to the reports of this series will be found in a detailed analysis of the deaths registered in institutions for the sick or infirm. In previous years these deaths had been shown separately from those occurring at home, but the scope of classification has now been considerably extended. Thus, in the present report the *ages at death* are shown in relation to the place of death, whether hospital or workhouse, and in the two preceding reports the *causes of death* are indicated in the same relation. The present tables reveal a great difference in the age distribution of deaths in the several classes of institution—the deaths in hospitals being mainly those of the young and in workhouses mainly those of the aged. A noteworthy feature in these tables is the relatively excessive proportion of institution deaths in the metropolis, amounting to 46·5 per cent. of all males and 40·9 per cent. of all females, as against percentages of 23·5 and 18·8 respectively in the provinces generally. Still more worthy of note are the figures respecting age. At ages up to the sixty-fifth year the male deaths in institutions average half the total deaths in the metropolis at those ages, whilst at age 5–15 such deaths constitute two-thirds of the total. The proportion of male deaths in institutions exceeds that of female deaths at every age group, but at ages between 5 and 45 half the deaths of London females occur in institutions. In early infancy and extreme old age institution deaths are comparatively few, except in London, where they are never less than 30 per cent. of the total.

Causes of Death.—General Diseases.

Dr. Stevenson prefaces his remarks on the causes of mortality by reaffirming the necessity of reference to the "Manual" issued by his department in 1912 for the purpose of explaining the newly adopted scheme of death tabulation, and of facilitating its application to the conditions of English statistics This scheme supersedes the method originally established by Dr. Farr and followed in the central office ever since its inception 70 years ago. Incidentally, the manual supplies information respecting the methods now pursued in the central office in the compilation of mortality returns; this is essential to thorough appreciation of their significance.

From a public health view-point the interest attaching to the statistics of infectious diseases has been greatly increased by the publication of authoritative returns showing the distribution of notifiable diseases throughout England and Wales. In the present report the returns have been arranged to show, for the several classes of area in the four geographical divisions of the country, the "prevalence" of the notified cases of particular diseases in terms of estimated population, and also their "fatality," as expressed by the ratio of deaths to cases notified. This information is, of course, supplementary to the returns of "mortality" as compared with the numbers living, which have appeared in previous years.

Enteric Fever.

In the year under review this disease was responsible for a mortality equal to 41 per 1,000,000 living in England and Wales, as compared with 44 per 1,000,000 in 1912. These are the lowest rates on record; in no year previous to 1907 had the rate been less than twice its present amount. Very unequally distributed is the loss of life from enteric fever. The usual association of excessive mortality with urban conditions was observed throughout the year. Lancashire, Northumberland, and Flintshire were the counties with the highest mortality, and the county boroughs similarly placed were Wigan, Devonport, and Kingston-upon-Hull. Not one of these boroughs had experienced a mortality of less than 110 per million in either of the last three years. Facts such as these indicate that the persistence of excessive enteric fever mortality in England is largely due to the backward sanitary position of a small number of areas. The returns of notified enteric cases in the country generally show that in 1913 both the prevalence and the fatality were lower than in the previous year. In the north, where the attacks in former years had been more numerous than elsewhere, and in Wales there was slightly increased prevalence, with some decline in the midlands and the south. Fatality was highest in the north, the region of greatest prevalence. The position of London was particularly favourable in regard both to prevalence and to fatality. In recent years there has been a marked increase in the hospital treatment of enteric fever, and there is little doubt that by diminishing opportunities for spread of infection hospital isolation has been an important factor in limiting the prevalence of this disease. The figures are not available for the year under notice, but those for previous years show that of the total deaths from enteric fever there occurred in hospitals 50 per cent. in 1911 and 48 per cent. in 1912.

Scarlet Fever.

The mortality from this disease in England and Wales was at the rate of 57 per 1,000,000 living at all ages, and of 171 per 1,000,000 at ages under 15 years. With the exception of the very low rates of the two preceding years these are the lowest on record. The decline of scarlet fever mortality during the last half century is very remarkable. Up to 1906 no year had experienced a mortality less than double that of 1911. The local distribution of mortality varies little from year to year. In the last three years the rate has been twice as high in the great towns as in the rural districts. The north of England has suffered a mortality which is double that of the south, which latter is below that of any other part of the country. The notification returns indicate that the disease was more prevalent in 1913 than in either 1911 or 1912. This increase, however, was accompanied by a decrease in fatality, which was only 16 per 1000 cases, against 18 and 19 in the two preceding years. In the north the fatality was higher than in the midlands or in the south. The extent to which scarlet fever was isolated in hospital cannot be given for 1913, but in the year immediately preceding about 65 per cent. of the deaths occurred in hospital. In London the proportion was as high as 94 per cent., whilst in the rural districts it did not exceed 40 per cent.

Diphtheria and Croup.

Inasmuch as in 1911–13 not less than 97 per cent. of the mortality from this cause occurred at ages under 15 years, the statistics now given relate mainly to that period of life. The distribution of diphtheria mortality throughout the country is given for each of the last three years, from which it appears that apart from a general tendency to increase of mortality with increase of urbanisation, there are no striking differences to record. Although the fatality from diphtheria was higher in the north than in other areas the prevalence of the disease as indicated by notification was at its lowest in that region. From this it does not follow that the disease was either severer or less satisfactorily treated there than elsewhere, for the number of notifications has recently been increased by cases of a milder type, the nature of which can only be established by bacteriological examination. While the practice of making such examinations has been more general in the south than in the north or in Wales, this fact alone may account for the much higher prevalence and lower fatality in the former region. About 80 per cent. of the London deaths from this cause occur in the hospitals of the Metropolitan Asylums Board. It is therefore instructive to learn how low is the fatality of cases now treated there in comparison with that of the years preceding the introduction of antitoxin treatment. Since 1890–93 the case fatality has fallen from 304 per 1000 admissions in that period to 65 per 1000 in 1913. About half the deaths from diphtheria and croup in England and Wales are registered in public institutions.

Tuberculosis.

In the year under notice tuberculous affections in the aggregate accounted for a mortality at the rate of 1340 per million living, which is less than that of any previous year, and is equal to 9·8 per cent. of the mortality from all causes. This satisfactory fall has occurred notwithstanding unfavourable changes in the age constitution of the population. The standardised death-rate of 1913 shows a reduction of 15 per cent. on the average of the quinquennium ended in 1910. The fall was shared equally by both sexes, but the mortality of males exceeded that of females by about one-third. The excess was greater in town than in country; it was 68 per cent. in London and 41 per cent. in the county boroughs, but only 8 per cent. in the rural districts. Urban conditions of life increase the risk of tubercle among males much more than among females, the excess of the London rate over that of the rural districts being 91 per cent. for the former sex but only 33 per cent. for the latter. The adverse effect of town life is especially conspicuous at ages after the fifteenth year, at which age work away from home commonly begins. In childhood this effect is not observed.

Tuberculous phthisis contributed 75 per cent. to the total mortality from tuberculosis in the year under notice, the deaths corresponding to a rate of 1004 per million living at all ages, and to 7·3 per cent. of the total mortality. The local distribution of phthisis is similar to that of tuberculosis generally. There is the same tendency to increase of mortality with urbanisation, which is strongly marked among males and less so among females, so that the excess of male over female mortality increases regularly from the rural districts to the metropolis.

The period of maximum phthisis mortality occurs earlier in life in the rural districts than in the towns, and earlier among females than among males. In the metropolis an excess of mortality is experienced by old men and also by old women. Moreover, the excess of male over female mortality, as well as its increase with urbanisation, is there especially characteristic of old age.

It will be seen by the tables that the excess of male mortality which is so remarkable in England does not exist in Wales, where the rates for both sexes are about equal. In each of the last three years the north of England records a high mortality for both sexes in its great towns, but not elsewhere. The position of the midlands generally is satisfactory for both sexes.

Tuberculous meningitis caused less loss of life in 1913 than in any previous year. Its death-rate has been steadily declining for the last 60 years, and now stands at one-third of its former amount. Such a decline in a period of rapidly increasing urbanisation is the more remarkable because this affection is exceptionally associated with urban conditions of life. That this association holds good for the younger ages only is shown by a table limited to ages under 15 years, within which period 89 per cent. of the total deaths occur. In 1911–13 the mortality in London at ages under 5 was more than double that of the rural districts generally, and at ages 5–10 the excess was almost as great, but at 10–15 the rates for London and the rural districts were practically equal.

Abdominal tuberculosis, including tabes mesenterica, has been decreasing rapidly as a cause of death for the last 30 years, and now accounts for only one-third of the loss of life formerly attributed to it.

Malignant Disease.

Unfortunately no check can as yet be discerned on the increase of cancer or malignant disease which has been experienced in this country for many past years. On the contrary, the loss of life from this cause was greater in 1913 than in any previous year on record. The mortality among males was equal to 947 per million living, and among females to 1155 per million, as compared with rates of 913 and 1117 respectively in the year 1912. The cancer-rates have been standardised for the country as a whole and for the aggregate urban districts as well as for the four geographical divisions dealt with throughout this report. The tables show a constantly increasing mortality in proportion to urbanisation, which is more serious in the case of males than of females. In Dr. Stevenson's judgment "it is quite conceivable that differences of the dimensions shown may be due to the better facilities for diagnosis in the urban areas, where a much larger proportion of the deaths occur in institutions in which post-mortem examination is the rule, than, as in private practice, the exception." The considerable increase of mortality now recorded is very uniform, being common to both sexes in every class of area. It is also widely spread over the different age periods, the chief exceptions being in the case of women at very advanced ages. The excess of female mortality over that of males is concentrated mainly on the ages 25–55. At other ages there is either practical equality or a male excess, as at ages from 60 to 85 in the country generally. The deaths from malignant disease occurring in institutions are shown separately from those in the home, the object being to compare the experience of hospitals, where presumably the details of the cause of death have been generally confirmed by necropsy, with the certification of other deaths from causes where such facilities are as a rule wanting.

The increase of mortality from cancer of various organs differs. In both sexes the most rapid rates of increase are furnished by cancer of the alimentary tract, especially the intestines and stomach. Diseases of the female breast also claim a rapidly increasing number of victims, while mortality from uterine cancer is diminishing. The relation of mortality to marital condition is discussed in the text. It would appear that childbearing increases the risk of uterine and diminishes that of mammary cancer; it may therefore be expected that the present decrease of fertility will be accompanied by an increase of mammary rather than of uterine disease. Notwithstanding the general increase the mortality from cancer of the liver remains stationary. Secondary growths are mentioned with especial frequency in cases of breast cancer. Deaths thus certified amount to 33 per cent. in the case of the breast, whereas in the case of most other important sites the proportion falls short of 10 per cent. The conditions observed as complicating death from cancer are summarised in the report. Of those which do not appear dependent on the existence of a growth the most important are tuberculosis, diabetes, diseases of the circulatory system, Bright's disease, and childbirth.

MEDICINE AND THE LAW.

The Verdict "Guilty but Insane."

THE Court of Criminal Appeal, following its own ruling in R. *v.* Felstead, recently dismissed an appeal, or rather refused to hear it, in the case of a man named Taylor indicted for unlawful wounding at Worcester quarter sessions. Taylor had been for two years a certified lunatic in Powick Asylum, of which he was an inmate when the assault with which he was charged was committed. When he was put up to plead he made rambling statements, but "after some little pressure from his counsel," to quote from the *Times* report, he pleaded guilty. Counsel for the prosecution, however, suggested that a plea of "Guilty" in such circumstances ought not to be accepted, and urged that a plea of "Not Guilty" should be entered, and the prisoner tried in order to obtain the verdict of the jury as to the state of his mind at the time of the offence. This proposal was adopted, the case was gone into, and a verdict of "Guilty but insane" was returned. The prisoner accordingly was ordered to be detained during His Majesty's pleasure, a case being stated by the bench in order to allow a decision to be obtained whether in the circumstances described above the verdict mentioned could be returned. In the Court of Criminal Appeal the preliminary point was taken, that in accordance with the decision in Felstead's case the verdict "Guilty but insane" did not constitute a conviction, and that Taylor not having been convicted could not appeal. Taylor's counsel, on the other hand, relied upon his having pleaded guilty, and declared that he had never withdrawn that plea. He argued that being convicted on his own confession his client had the right to appeal. The court upheld the preliminary point mentioned and decided that it had no jurisdiction to hear the appeal, basing its decision on the fact that the case had been heard and the verdict recorded. The Lord Chief Justice, however, in delivering judgment, expressed the opinion that through the law being as Felstead's case declared it to be, difficulties arose which were probably not foreseen when the Criminal Appeal Act, 1907, was passed. These difficulties, his lordship said, could only be removed by the legislature, which some day might see fit to amend the law. The result in this case was that no decision was given as to the question which the appellant's counsel tried to raise, that when once the prisoner had pleaded "Guilty" the court had no right to enter a plea of "Not Guilty" and try the question of his sanity. There may be a certain convenience in this course being adopted, for it can hardly be right that a lunatic with dangerous propensities should be able by saying the word "guilty" to escape the means provided by the law for restraining him in the future. At the same time it is hardly satisfactory that in so important a case as one involving the question of a man's sanity neither the exercise of its discretion by the court nor the verdict of the jury should have been capable of being appealed against, and this not through the deliberate intention of the legislature but owing to an oversight.

The London Insurance Committee and the Allotment of Insured Persons.

The action of Mr. H. Bazett against the London Insurance Committee, based upon the failure of the latter to assign to medical men on the panel insured persons who had not selected their medical attendants, was tried by Mr. Justice Darling and a special jury recently. The plaintiff asked for a mandamus ordering the Insurance Committee to assign the persons referred to, as contemplated by the Insurance Act, and claimed damages for the Committee's failure to do so. The defendants alleged that it was absolutely impossible for them to assign the insured persons who had not chosen medical men, the system of registration being so involved and the insured population of so fluctuating a character, the constant changes of address rendering it extremely difficult, if not impracticable, to keep abreast of the alterations. It was stated by the clerk of the committee that at one time 300 clerks had been engaged upon the registers. The same witness said that out of 1200 medical men interested only five had objected to the method adopted for distributing the surplus funds. The jury intimated that they had made up their minds in favour of the defendants, but Mr. Bazett persevered with his case a little longer. Mr. Justice Darling finally intimated that in his view the legal maxim applied, "*Lex non cogit ad impossibilia,*" and that the defendants had done everything in their power to carry out the regulations. The jury then found for the defendants. Apparently those who framed an Act of Parliament have made the mistake of imposing an impossible task upon the bodies to whom the task of administration was to be entrusted, and a way out of the difficulty has been found which must be accepted, although, in the opinion of Mr. Danckwerts, it was not legally justifiable. Presumably it would not be impossible so to increase the clerical staff of even the London Committee as to enable the work to be done, but the question would naturally arise whether the result would be worth the cost involved.

THE NATIONAL INSURANCE ACT.

Panel Patients during War.

AT a meeting of the West Riding Insurance Committee recently the question of the provision of medical aid for panel patients whose selected practitioner had undertaken military service was raised by a member, Mr. J. W. Waterhouse. He suggested that where a member of the panel had gone to the front the insured persons affected should be entitled to medical benefit from any practitioner in the immediate neighbourhood, or at least should be allowed to make their choice, and be assigned accordingly. Dr. J. Russell observed that the practice had been for the committee to send a post-card to the patient giving him the name of the medical man who would take him over, and it was stated that this practice had worked well. Probably in many instances patients are satisfied to do as they are told, but the matter is not an easy one, and several considerations are involved. On the one hand a medical man may have undertaken the work of a friend, intending to safeguard his interests with regard to patients whether insured or not, and from the point of view of the absent practitioner it would be right that his patients should all be attended by his selected substitute. There can, however, in such a case be no compulsion except for insured patients, and it may be questioned whether there ought to be for them, when it is remembered that they originally selected a particular practitioner and that free choice of a medical attendant is one of the points upon which the medical profession has all along insisted. Let us hope that if any difficulty arises it will not be of long duration, and that at any rate there will be no question as to securing the return of the insured to their original medical attendants when these resume civil life. At the recent general meeting of the Camberwell Insurance Practitioners' Association a resolution was carried "that insured persons who may wish to transfer from the lists of doctors on active service should not be accepted on their lists by other doctors under any circumstances." It was pointed out by Dr. G. B. Batten that this implied that a medical man should refuse to treat as an insured person the patient of a colleague on the panel after the war was over. It did not imply refusing to treat such patients during the war; they must only not be accepted permanently.

Hearts of Oak Society and Insurance.

At the annual meeting of the Hearts of Oak Benefit Society it was stated, with regard to State members, that so far as men were concerned the payments for sickness benefit had amounted to 92 and 91 per cent. of the sums estimated for 1913 and 1914 respectively. The sickness benefit for women had been slightly in excess of what had been expected, amounting to 106 per cent. of the estimate in 1913 and 108 per cent. for 1914. The number of members of the society before the passing of the Insurance Act, 1911, who under it had become insured persons had been 176,000, and of these only 96,000 had reduced their contributions. The Act had, however, imposed great difficulties upon the society, and had accentuated the problem of over-insurance.

Excessive Prescribing: Difficulties of Investigation.

The London Panel Committee, at a special meeting on June 1st, decided, in view of the heavy expenditure of time and money involved in the investigation of representations by the Pharmaceutical Committee as to alleged excessive prescribing, to limit in future the amount of time spent upon this work. The Pharmacy Subcommittee pointed out that representations had yet to be received in respect of the second part of 1914, and no useful purpose was served in discussing with practitioners prescriptions written more than a year ago. It was highly desirable that every practitioner on the panel should be informed monthly of the average cost of his prescriptions. If investigations into about 500 practitioners' scripts were continued for a whole year, as at present, the funds of the committee would be swallowed up in dealing with this branch of its work. The committee decided to inform the Pharmaceutical Committee that it would deal with the most recent prescriptions submitted and that for the present the number of separate cases investigated must be limited to 50 in each three months. The committee also resolved to withdraw from the arrangement by which it shares with the Insurance Committee and the Pharmaceutical Committee the cost of the examination of prescriptions. The reasons given were that no onus rested on the Panel Committee to contribute towards mere arithmetical checking, and that the work done under this arrangement did not save the time of the Panel Committee when investigating allegations of excessive prescribing.

The London Panel Committee and the War.

The London Panel Committee has appointed a special section to consider and report as to the steps which should be taken to enable practitioners on the panel to render the greatest possible assistance in connexion with the war. Inquiry is to be made as to the manner in which the Panel Committee may most usefully coöperate with the British Medical Association in its efforts in the matter. Dr. C. W. Hogarth has resigned the chairmanship of the Panel Committee.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned has been granted a commission as temporary Surgeon in His Majesty's Fleet: John Paxton (dated May 21st).

The seniority of temporary Surgeon Jack Rupert Law Willis has been antedated to August 22nd.

The following appointments have been notified:—Temporary Surgeons: M. O. Raven to the hospital ship *China;* and W. L. Coullie to the *Birmingham.*

ARMY MEDICAL SERVICE.

Surgeon-General Sir David Bruce, C.B., F.R.S., is retained on the Active List, under the provisions of Article 120, Royal Warrant for Pay and Promotion, and to be supernumerary (dated May 29th).

Captain Charles A. Ballance, M.V.O., Royal Army Medical Corps, Territorial Force, to be temporary Colonel (dated May 18th).

ROYAL ARMY MEDICAL CORPS.

The undermentioned are granted the temporary rank of Major whilst serving with the Northumberland War Hospital:—Hector Duncan Macphail (dated May 12th), Cuthbert Umfreville Laws (dated May 16th), and Charles D'Oyly Grange (dated May 17th).

The undermentioned are granted temporary honorary rank whilst serving with the British Red Cross Society in France:—As Lieutenant-Colonel: Edward Stewart (dated May 29th). As Lieutenant: Edward Harman Hicks (dated May 29th).

Major Harold S. Peeke, Reserve of Officers, Royal Army Medical Corps, to be temporary Lieutenant-Colonel whilst serving with the Liverpool Merchants' Mobile Hospital (dated March 24th).

Edwin Goodall to be temporary Lieutenant-Colonel whilst employed at the Welsh Metropolitan War Hospital (dated May 1st).

The undermentioned are granted temporary rank whilst employed at the Lord Derby War Hospital:—As Lieutenant-Colonel: Alexander Simpson (dated April 1st). As Major: Frederick Millar Rodgers (dated May 24th). Alexander McLean Cato to be temporary Lieutenant (dated May 21st).

The undermentioned having ceased duty with the Queen Mary's Convalescent Home for British Officers, Nice, relinquish their commissions:—Dated 30th April: Temporary Major Samuel Macken and temporary Captains Henry S. C. Starkey and Frederick P. Nunneley.

Temporary Lieutenant John Sydney Rowlands to be temporary Captain whilst serving with the Welsh Hospital (dated May 28th). Rupert Farrant to be temporary Lieutenant (dated May 13th).

The appointment to a temporary Captaincy of John P. Campbell, late Captain 10th (Cyclist) Battalion, The Royal Scots (Lothian Regiment), Territorial Force, is antedated to April 1st, 1915).

The undermentioned to be temporary Lieutenants:—Dated March 12th: James Rashid Wortabet. Dated March 21st: Charles Montagu Harris. Dated March 23rd: Norman Edward Packer, Charles Owen Donovan, John Thomson Anderson, Robert Burnside Carter, Eric Phillip Blashki, John Lloyd Digby, Norman McAlister Gregg, Eustace Townley Pinhey, Norman Walford Broughton, Sydney William Gardiner Ratcliff, Clive Farranridge, and Arthur Wilmot Raymond. Dated March 26th: Harold John Penny, John Joseph O'Neill, and Brian William Wibberley. Dated April 4th: Bruce Maitland Carruthers, Gordon Alick Renwick, John Roberts MacCulloch, Charles Goldsborough Adams, Walter Francis Stewart Yeates, Charles Horsfall Armitage, Charles Reginald Ralston Huxtable, Francis James Fahy, Hugh Alton Chandos Wall, and Archibald Warden Graves Murray. Dated April 6th: Ernest Robertson, Basil Walter Cohen, Norman Charles Talbot, Colin Hasler Martin, Alexander Hugh Melville, Frederick Harold Moran, Archibald Simpson Anderson, and Harold Whitfield Ward. Dated April 7th: Hugh Meyrick Meyrick-Jones and William Stuart Hawthorne. Lewis Wilson Shelly (dated May 24th).

The undermentioned to be temporary Lieutenants whilst serving with the British Red Cross Hospital, Netley: Gordon Normanby Brandon (dated May 18th) and William Burt (dated May 23rd).

Temporary Lieutenant Isidore J. Block relinquishes his commission (dated May 4th).

SPECIAL RESERVE OF OFFICERS: SUPPLEMENTARY TO REGULAR UNITS OR CORPS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank:—Peter MacCallum, Gilbert W. Rose, Donald C. Scott, James S. Robinson, and Stanley B. King.

Cadet Serjeant George Gibson Cooper, from the Glasgow University Contingent, Officers Training Corps, to be Lieutenant (on probation).

TERRITORIAL FORCE.

Army Medical Services.

Captain William J. Hoyten, from 1st East Anglian Field Ambulance, to be Deputy Assistant Director of Medical Services, South Midland (Reserve) Division, with the temporary rank of Major.

Royal Army Medical Corps.

3rd Southern General Hospital: Hugh Anthony Bulstrode Whitelocke to be Lieutenant.

1st Lowland Field Ambulance: Frank Morton Robertson to be Lieutenant.

2nd Lowland Field Ambulance: To be Lieutenants: William Grove and William Jack Scade.

1st North Midland Field Ambulance: Captain Frederick W. Johnson, from Attached to Units other than Medical Units, to be Major (temporary).

3rd Northern General Hospital: Captain Arthur G. Yates to be Major.

1st Southern General Hospital: Major James T. J. Morrison is restored to the establishment. To be Lieutenants: Herbert Charles Horace Bracey and Arthur Harry Newton. Edward Musgrave Woodman (late temporary Lieutenant, Royal Army Medical Corps) to be Captain, whose services will be available on mobilisation.

2nd Southern General Hospital: Lieutenant James G. McLannahan, from 3rd South Midland Field Ambulance, to be Captain on the permanent personnel.

Sanitary Service: Alexander Gregor to be Captain, whose services will be available on mobilisation.

1st London (City of London) Sanitary Company: Lieutenant John H. Baldwin to be temporary Captain. To be Lieutenants: Private John Golding, from the 28th (County of London) Battalion, The London Regiment (Artists Rifles), and Gilbert Norman Anderson.

Lowland Divisional Sanitary Section: Lieutenant Thomas J. Mackie, from Attached to Units other than Medical Units, to be Lieutenant.

Lowland Casualty Clearing Station: Major George Robert Livingston, from Attached to Units other than Medical Units, to be Major. To be Lieutenants: Lieutenant Stuart Robertson, from the 1st Lowland Field Ambulance; Lieutenant Stephen Anderson MacPhee, from the 2nd Lowland Field Ambulance; Lieutenant Adam Rankine, from the 1st Lowland Field Ambulance; and William Cullen.

West Riding Casualty Clearing Station: Major Louis P. Demetriadi, from Attached to Units other than Medical Units, to be Lieutenant-Colonel (temporary).

2nd Home Counties Field Ambulance: Major Antony A. Martin to be temporary Lieutenant-Colonel.

West Riding Divisional Sanitary Section: Captain Cuthbert B. Moss-Blundell, from list of Sanitary Officers available on mobilisation, to be Captain.

Northumbrian Casualty Clearing Station: Major William A. Wetwan to be temporary Lieutenant-Colonel.

North Midland Mounted Brigade Field Ambulance: Arthur Avent (late Lieutenant of this Unit) to be Captain (temporary).

Yorkshire Mounted Brigade Field Ambulance: Captain and Honorary Major Alfred Hugh Benson, Retired List (late Royal Army Medical Corps (Militia)) to be Captain (temporary). Joseph Charles Denvir to be Dieutenant.

3rd North Midland Field Ambulance: James Edwin Wilson to be Lieutenant.

1st West Riding Field Ambulance: Lieutenant Herbert B. Pope to be temporary Captain.

5th Northern General Hospital: The undermentioned to be Captains, whose services will be available on mobilisation: Everard Harrison, Henry Mason, Neville Ivens Spriggs, Ernest William Holyoak, and Frederick Valentine Milburn.

Highland Casualty Clearing Station: John Innes (late Captain, 2nd Highland Field Ambulance) to be Captain (temporary).

2nd East Anglian Field Ambulance: Captain Dudley William Boswell to be temporary Major.

3rd Home Counties Field Ambulance: John Francis Molyneux to be Lieutenant.

2nd West Lancashire Field Ambulance: Captain Walter L. Hawksley to be temporary Major.

3rd Lowland Field Ambulance: Captain James Young to be temporary Major.

4th London General Hospital: Major William A. Turner is restored to the establishment.

1st Northern General Hospital: William Stott to be Lieutenant.

1st Western General Hospital: Walter Charles Oram to be Captain, whose services will be available on mobilisation. Charles Philip Brentnall to be Lieutenant. Leslie Oldershaw to be Lieutenant.

2nd Western General Hospital: Harry Platt to be Captain, whose services will be available on mobilisation.

Attached to Units other than Medical Units.—Major Robert J. R. C. Simons is seconded. To be Captains: Temporary Captain John B. Bate and Lieutenant Hugh Paterson. To be Lieutenants: David Alexander Ross Haddon (late Lieutenant, 9th (Highlanders) Battalion, The Royal Scots (Lothian Regiment)), Lieutenant John J. Porter (from 3rd Welsh Field Ambulance), William Hall Calvert (late Surgeon-Lieutenant, 1st Roxburgh and Selkirk (The Border Rifle Volunteer Corps)), John K. Brownlees, Leonard Herbert Henry Boys, Thomas Sprot Allan (late Surgeon-Lieutenant, 1st Volunteer Battalion, Middlesex Regiment), and William Joseph Lacy-Hickey. Lieutenant George W. Mason resigns his commission on account of ill-health.

TERRITORIAL FORCE RESERVE.

Royal Army Medical Corps.

Lieutenant-Colonel William McGregor Young, from the West Riding Casualty Clearing Station, to be Lieutenant-Colonel.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8530 births and 5340 deaths were registered during the week ended Saturday, May 22nd. The annual rate of mortality in these towns, which had steadily declined from 19·9 to 14·2 per 1000 in the six preceding weeks, rose in the week under notice to 15·4 per 1000 of their aggregate population, estimated at 18,136,180 persons at the middle of last year. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 17·0, against a corresponding rate of 17·7 per 1000 in London. The annual death-rate in the week under review ranged from 7·9 in Wimbledon, 8·6 in Oxford, 8·8 in Edmonton and in Rhondda, 9·3 in East Ham, in Reading, and in Bolton, and 9·4 in Leyton, to 23·9 in Wigan, 25·1 in Dewsbury, 25·8 in Gateshead, 28·9 in Middlesbrough, and 29·9 in Walsall.

The 5340 deaths from all causes were 386 in excess of the number in the previous week, and included 603 which were referred to the principal epidemic diseases, against numbers declining from 711 to 484 in the three preceding weeks. Of these 603 deaths, 309 resulted from measles, 137 from whooping-cough, 70 from infantile diarrhœal diseases, 51 from diphtheria, 20 from scarlet fever, 15 from enteric fever, and 1 from small-pox. The mean annual death-rate from these diseases was equal to 1·7, or 0·3 per 1000 more than in the previous week. The deaths attributed to measles, which had been 392, 276, and 238 in the three preceding weeks, rose to 309 in the week under notice, and caused the highest annual death-rates of 2·6 in St. Helens, 2·7 in Wolverhampton, 3·5 in Gateshead, 4·0 in Barrow-in-Furness, 4·2 in Sheffield, 4·4 in Sunderland, 5·5 in Walsall, and 7·0 in Middlesbrough. The deaths referred to whooping-cough, which had steadily declined from 167 to 105 in the six preceding weeks, rose to 137, and included 41 in London, 8 each in Wigan and Salford, 7 in Liverpool, 5 in Leeds, and 4 each in Bristol, Manchester, and Sheffield. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 73, 67, and 57 in the three preceding weeks, rose to 70, of which 15 were registered in London, 7 in Liverpool, 6 in Manchester, and 4 in Birmingham. The deaths attributed to diphtheria, which had been 56, 51, and 48 in the three preceding weeks, rose to 51, and included 15 in London, and 3 each in Manchester and Sheffield. The deaths referred to scarlet fever, which had been 34, 30, and 25 in the three preceding weeks, further fell to 20, of which 5 occurred in London, and 2 each in Stoke-on-Trent and Manchester. The fatal cases of enteric fever, which had been 12, 12, and 11 in the three preceding weeks, rose to 15, and included 4 in London and 2 in Leeds. The death from small-pox was registered in Bristol.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 2377, 2384, and 2332 at the end of the three preceding weeks, had further declined to 2286 on Saturday, May 22nd; 320 new cases were admitted during the week, against 316, 307, and 270 in the three preceding weeks. These hospitals also contained on the aforementioned date 1123 cases of diphtheria, 158 of measles, 55 of enteric fever, 12 of whooping-cough, and 1 of small-pox. The 1288 deaths from all causes in London were 33 in excess of the number in the previous week, and corresponded to an annual death-rate of 14·9 per 1000. The deaths referred to diseases of the respiratory system, which had declined from 469 to 227 in the five preceding weeks, further fell to 212 in the week under notice, but were 24 in excess of the number recorded in the corresponding week of last year.

Of the 5340 deaths from all causes in the 96 towns 235 resulted from different forms of violence and 380 were the subject of coroners' inquests, while 1546 occurred in public institutions. The causes of 46, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, and in 68 other smaller towns. Of the 46 uncertified causes of death, 9 were registered in Birmingham, 5 in Gillingham, 4 in Liverpool, and 3 each in Southport and Warrington.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1121 births and 724 deaths were registered during the week ended Saturday, May 22nd. The annual rate of mortality in these towns, which had been 20·2, 18·1, and 17·9 per 1000 in the three preceding weeks, further declined to 16·1 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 18·9, against a corresponding rate of 17·0 per 1000 in the large English towns. Among the several towns the death-rate in the week under review ranged from 4·9 in Clydebank, 8·9 in Kirkcaldy, and 11·4 in Aberdeen, to 18·6 in Ayr, 18·8 in Motherwell, and 19·1 in Perth.

The 724 deaths from all causes were 83 fewer than the number in the previous week, and included 90 which were referred to the principal epidemic diseases, against numbers declining from 150 to 117 in the three preceding weeks. Of these 90 deaths, 40 resulted from whooping-cough, 36 from measles, 6 from scarlet fever, 5 from infantile diarrhœal diseases, 2 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·0, against 1·7 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 82, 65, and 45 in the three preceding weeks, further declined to 40 in the week under notice, and comprised 22 in Glasgow, 11 in Edinburgh, 4 in Dundee, 2 in Falkirk, and 1 in Motherwell. The deaths referred to measles, which had increased from 19 to 49 in the five preceding weeks, fell to 36, of which 26 occurred in Glasgow, 4 in Aberdeen, 3 in Dundee, 2 in Falkirk, and 1 in Perth. The fatal cases of scarlet fever, which had been 11, 7, and 6 in the three preceding weeks, were again 6 in week under review, and comprised 5 in Glasgow and 1 in Aberdeen. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 9, 15, and 9 in the three preceding weeks, further fell to 5, of which 2 were registered in Glasgow. The fatal cases of diphtheria were recorded in Glasgow and Edinburgh, and that of enteric fever in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 153, 118, and 121 in the three preceding weeks, fell to 117 in the week under notice, but were 10 in excess of the number recorded in the corresponding week of last year. The deaths attributed to violence numbered 21, against 23 and 26 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,212,380 persons at the middle of this year, 680 births and 425 deaths were registered during the week ended Saturday, May 22nd. The annual rate of mortality in these towns, which had been 19·1, 19·9, and 18·8 per 1000 in the three preceding weeks, fell to 18·3 per 1000 in the week under notice. During the first seven weeks of the current quarter the mean annual death-rate in these towns averaged 20·6, against corresponding rates of 17·0 and 18·9 per 1000 in the English and Scotch towns respectively. The death-rate in the week under review was equal to 20·8 in Dublin (against 14·9 in London and 18·0 in Glasgow), 16·7 in Belfast, 21·8 in Cork, 12·7 in Londonderry, 10·8 in Limerick, and 30·4 in Waterford, while in the 21 smaller towns the mean rate was equal to 16·1 per 1000.

The 425 deaths from all causes were 13 fewer than the number in the previous week, and included 24 which were referred to the principal epidemic diseases, against numbers declining from 41 to 27 in the four preceding weeks. Of these 24 deaths, 9 resulted from measles, 5 from whooping-cough, 4 each from scarlet fever and infantile diarrhœal diseases, and 2 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 1·0, against corresponding rates of 1·7 and 2·0 per 1000 in the English and Scotch towns respectively. The deaths attributed to measles, which had declined from 13 to 4 in the four preceding weeks, rose to 9 in the week under notice, and comprised 4 each in Dublin and Belfast and 1 in Cork. The deaths referred to whooping-cough, which had been 9, 9, and 10 in the three preceding weeks, fell to 5, and included 3 in Dublin. The 4 fatal cases of scarlet fever, of which 3 occurred in Waterford and 1 in Lisburn, were 2 in excess of the average in the earlier weeks of the quarter. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 10, 9, and 8 in the three preceding weeks, further fell to 4, and were all registered in Dublin. The fatal cases of diphtheria were recorded in Dublin and Kilkenny.

The deaths referred to diseases of the respiratory system, which had been 84, 76, and 82 in the three preceding weeks, further rose to 93 in the week under notice. Of the 425 deaths from all causes, 137, or 32 per cent., occurred in public institutions, and 8 were attributed to different forms of violence. The causes of 12, or 2·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the large English towns the proportion of uncertified causes did not exceed 0·9 per cent.

Correspondence.

"Audi alteram partem."

THE PULSUS ALTERNANS.

To the Editor of THE LANCET.

SIR,—Dr. C. O. Hawthorne's interesting paper in THE LANCET of May 29th opens up a question that I have often asked myself: When is a pulsus alternans not a pulsus alternans, so far as its now usually accepted gravity of prognosis goes? Dr. Hawthorne, alluding to this, gives at the end of his paper the case of a young woman who has not died as she should have done, and his earlier remarks and the tracings given from sphygmograph and manometer seem to me to suggest the answer. In thus showing that a pulsus alternans is of quite a common occurrence, he describes what surely must be the common experience of us all. Everyone must be familiar with the fact that at the radial pulse at the wrist every heart beat need not have an equivalent value, and this variation may range from complete intermission down to a lessening of force that cannot be recognised by the finger. One had almost said when we are dealing with a muscular organ such as the heart with the variety of minor details that energise it and detract from its nervous supplies, it could hardly be otherwise. This in nowise detracts from the value of the observation that there is a pulsus alternans that has a grave significance; it does go to show that one may expect at times a pulsus alternans that has not such an ominous outlook. And surely there must be many who have lived—well! to pre-senility—who have met with this condition many a time, with *a* form but not *the* grave form of pulsus alternans. I have also met occasionally with a sort of double pulsus alternans, two full beats followed by two small beats, that had no serious meaning.

Then how are we to distinguish between the two? I may leave others to answer this question. For myself I shall only venture to suggest that the serious form generally goes with signs of cardiac failure, whilst the alternation to which I am directing attention comes and goes—sometimes the rhythm may change two or three times in one examination—and maybe in quite young people who have no signs whatever of any cardiac distress. It is clearly a neuromuscular eccentricity of action that has no serious meaning. There are other points in Dr. Hawthorne's paper quite well worth taking up, and chief of them, to my mind, is the comparative value of the sphygmograph and the manometer. It has always seemed to me that the latter is a much less precise and reliable instrument than the sphygmograph which has so much yielded place to it. There can be no doubt that the facts of the pressure gauge, if so I may call the manometer, require the most careful valuation before drawing inferences therefrom.

I am, Sir, yours faithfully,

May 31st, 1915. JAMES F. GOODHART.

THE USE OF ATROPINE IN GASSED PATIENTS.

To the Editor of THE LANCET.

SIR,—I have just been reading Dr. Douglas V. Cow's article on this subject in THE LANCET of May 29th, and am particularly interested in his experiments. It had struck me that atropine might be of use, for I have taken it for acute bronchitis with the typical tightness across the chest and difficulty in breathing, and the mixture which used to give the greatest and quickest relief was one containing liq. atrop. sulph. ♏ ix. (which must be fresh) ad ℥ vi.; dose, ℥ss.

As a student, when making chlorine gas, although we used draught cupboards, I inhaled the gas rather too freely, and I well remember the tightness across the chest and uncomfortably difficult breathing it produced. The symptoms got worse after I had got home—about two hours after I should think. If I had to face chlorine, besides a mask I would provide myself with some liq. atrop. sulph., and I would take one dose before the cloud was on me. Dr. Cow's article would make me more inclined than ever to try atropine.

I am, Sir, yours faithfully,

IDA C. TENGELY, M.D. Lond.

Bishop's Stortford, May 29th, 1915.

THE MEDICAL DEFENCE UNION AND THE NATIONAL INSURANCE COMMISSIONERS.

To the Editor of THE LANCET.

SIR,—The letter written by Dr. A. E. Larking in your issue of May 29th makes it clear to me that he has failed to understand the position which the Medical Defence Union has taken up in respect of the surcharging of panel practitioners. The Union, by raising certain actions on behalf of members who are panel practitioners, is not attacking the National Insurance Acts or seeking to hamper the working of the Acts, but is merely endeavouring to protect its members against the effect of certain regulations of the Commissioners which the Union is advised are not in conformity with the Acts and are therefore *ultra vires*, and also to defend them against any action of the Insurance Committees which may appear to be arbitrary and wrongful. The Union therefore desires to take the opinion of the court as to the regulations and the procedure of Insurance Committees in administering the Acts.

We have already obtained a decision by the Commissioners in the Sheffield case, whereby the proceedings taken by the Panel Committee in surcharging were quashed at our instance.

In raising test actions in the High Court we are merely seeking to confirm and to extend the scope of that decision of the Commissioners. We are not seeking to destroy the Act; Parliament alone can either amend or annul it. As long as the Act exists it is imperative that we should, on behalf of our members, see that it is carried out legally and impartially; and we shall continue this duty, I trust, as long as the Act or the Medical Defence Union lasts. Dr. Larking appears to consider that the administration of the Act is unassailable; well, that is his opinion, but it is not mine, which is based upon the record of past successes in the High Court and elsewhere. If Dr. Larking could only see and read my daily correspondence from panel practitioners he would realise that a rapid rise of discontent as to the working of the Act is setting in all over the country.

I am, Sir, yours faithfully,

A. GEORGE BATEMAN.

Trafalgar-square, W.C., June 2nd, 1915.

To the Editor of THE LANCET.

SIR,—With regard to the letter by Dr. A. G. Bateman appearing in your issue of May 22nd, it will be granted that for the moment conservation of energy is imperative against the Empire's foe, and litigation at home should not be encouraged. Tact and judgment must be welcomed in this crisis for the greatest benefit to the community at the least expense, for the avoidance of surcharge for extravagance in prescribing for insured persons, and for steering clear of other technicalities in connexion with the working of the Act.

Is it possible to fix a Government estimate without a definite capitation grant for medicaments? The importance, however, of diet, regimen, pharmacology, and therapeutics, which form the staple practice of most practitioners, deserves a higher status in the curriculum, and such might with advantage be studied in the light of economy as well as efficiency and practicability. Knowledge and experience would then counteract indulgence in fancy and expensive prescribing.

I am, Sir, yours faithfully,

Gower-street, W.C., May 26th, 1915. DENNIS VINRACE.

To the Editor of THE LANCET.

SIR,—With regard to the letter on this subject appearing in your issue of May 29th, as a non-panel man I also strongly oppose using the funds of the Medical Defence Union for helping panel doctors out of the mire which they brought on themselves by signing the National Insurance pledge and then going back on their written word. Rather would I see it used in attempting to punish those half a dozen doctors who at the beginning started the rout. I thank heaven every day that I am no servant of any Insurance Committee, and that I have never gone back on my word.

I am, Sir, yours faithfully,

Streatham, S.W. May 30th, 1915. E. H. WORTH.

TREATMENT OF POST-INFLUENZAL COUGH BY BRITISH-MADE LYSOL.

To the Editor of THE LANCET.

SIR,—In company with thousands of others I had my yearly attack of influenza six weeks ago. I remained in bed two days, then went to work again as usual, but felt quite limp for the next three weeks; at the end of which time I began to pick up, but never lost a troublesome cough. It kept me awake at night, and in the morning I coughed until I had got rid of quantities of mucus of all consistencies. Where it all came from I am at a loss to understand; it collected in the upper part of the trachea and larynx. I had no chest symptoms.

I had on my table a bottle of British-made lysol sent as a sample. I was only interested in it because it was stated that used as an ointment, 10 per cent., it cured the worst cases of scabies, and I am getting it tried for mange and other skin troubles in dogs, so far with favourable results. Two days ago I was smelling at the bottle for some reason or other when it struck me that it might be good for my cough. I put about 4 oz. of boiling water into a small jug and poured on it about a drachm of the lysol and then inhaled the fumes for about five minutes. They made my nose and throat tingle a little but had no other unpleasant effect. I coughed a bit afterwards, then my cough stopped and has given me very little trouble since. I slept quite comfortably that night and coughed about twice the next morning instead of 30 or 40 times. I slept all the next night without waking and did not cough the next morning (May 16th).

On that day I tried myself pretty high. At 5 o'clock I paraded with about 200 other special constables at Marlborough-street police station; 99 of us were marched to Oxford Circus station, from there we went by train to Bow, marched from the railway station to the police station, were mustered with others in the station yard, and for the next four hours were in the streets in pouring rain and puddles galore under foot, or in the station in rooms reeking of wet clothing, with "draughts to the right of us, draughts to the left of us, draughts in front of us," and it may be added "draughts behind us." At 11 o'clock we were dismissed and returned to Marlborough-street by the same route. I got to bed at 12.45 and slept soundly till 7. The following day I had no cough.

There may have been other causes in operation—for one thing the weather got much milder and the wind went out of the north-east—but I was inclined to believe that inhalation of lysol cured my cough, and I was convinced of it after trying it again. A night later I was coughing again, and I feel I must sound a note of caution here. I fancy it may have a stupefying effect. I used the remedy in an ordinary spirit boiler, and as soon as a good cloud of steam began to rise put my nose and mouth well into it, and as near the boiling fluid as possible, and breathed deeply. In about two minutes I got drowsy and was very near dipping the end of my nose into the hot liquid, which would no doubt have proved an excellent restorative. There may be a source of fallacy here, because it was my bed-time, and I had been in the streets for the greater part of the two preceding nights, and could have slept standing up against a wall. Another thing, I am not sure that lysol used in too strong solution or inhaled for too long at a time may not be irritating to the respiratory mucous membrane, for on the last occasion I experienced something of the sensation which all of us who can remember when there were no other lucifer matches than the old-fashioned sulphur matches have felt if we tried to light a pipe or perform any such operation near the nose and mouth without waiting till the brimstone had burnt off.

I have given my experience for what it is worth, and hope it may be of use to others. I would suggest that the solution I used was too strong; it is somewhere between 1–60 and 1–30, very likely more, and I expect 1–100 is plenty strong enough. I did not measure the lysol; I have measured the whole mixture I used and it is 4 oz.

I am, Sir, yours faithfully,

CHARLES HIGGENS, F.R.C.S. Eng.

Brook-street, W., May 28th, 1915.

PS.—The inhalation might be tried in whooping-cough.

PRESENTATIONS TO MEDICAL MEN.—At a meeting of the members of the Totterdown and Imperial Divisions of the City of Bristol Corps, St. John Ambulance Brigade, held on May 21st, the Deputy Commissioner (Mr. J. S. Griffiths, M.R.C.S., L.R.C.P. Lond.), on behalf of the divisions, presented Mr. Joseph John Scammell Lucas, B.A., M.D. Lond., M.R.C.S., L.R.C.P., with a framed illuminated address and a walking stick "as a small appreciation of his services to the class and in the divisions for many years."—The members of the Brighton Division of the St. John Ambulance Association have just presented Mr. J. A. Amherst Orlebar, M.B., B.C. Cantab., with a silver cigarette box "as a token of their appreciation and esteem." Dr. Orlebar is leaving England on active service.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

SUBSCRIPTIONS OF THE WEEK.

WE call special attention to the generous and fruitful action of the Sunderland doctors who have paid into the Fund their fees for the examination of recruits. Last week we acknowledged from 14 of these gentlemen a donation in the aggregate amounting to no less than £142 2*s.* 6*d.* This week from 16 gentlemen the Fund has received a cheque for close upon £170, making over £300 received from this one source. Considering the numberless directions in which the work of medical men at the present moment is being increased in bulk and curtailed in emolument, the action of the Sunderland practitioners is a very open-handed one.

THE DISTRIBUTION OF THE FUND.

On Friday, May 28th, the recent official reports of three séances of the Aide et Protection aux Médecins et Pharmaciens Belges Sinistrés reached us through the kind offices of Professor Jacobs. This, it will be remembered, is the title of the committee formed in Belgium for ascertaining where the need is greatest among the Belgian doctors and pharmacists and for providing systematic relief. The president is Dr. Péchère, the secretaries M. Delacre and M. Laruelle, and the office is in Brussels; and it is upon this body, now strongly organised, that the British Fund is relying for distribution of its resources in Belgium.[1] When a representative of the Aide et Protection aux Médecins et Pharmaciens Belges met the Central Committee of the British Fund late in March he explained the way in which the Belgian Committee were compiling information to guide them in their work, and it was then decided that a substantial sum of money should be despatched immediately to Belgium, through the medium of certain banks and with the help of Mr. Herbert Hoover, the chairman of the National Relief Fund. An acknowledgment of this money was received from Dr. Péchère, but without details as to its distribution. These are now briefly supplied through the reports of séances held on April 15th, 22nd, and 29th. The physicians and pharmacists relieved include such cases as the following, which have been extracted from the fourth report of M. Laruelle dealing with the medical men, and from the report of M. Breugelmans dealing with pharmacists:—

To Dr. C——, of D——, it proposes to make a grant of 700 fr. Dr. C—— has had his house burnt with all its contents. He was obliged to take refuge at C—— and afterwards at W——. D——, the population of which has been reduced to one half, shelters now only a population which is deprived of resources, not affording, therefore, any opportunity to practitioners to gain their livelihood.

To Dr. R——, of T——, a grant of 400 fr. Our old colleague (aged 86 years) has seen his house with all its contents burnt. He was obliged to take refuge at M——. He would accept the temporary aid of the Committee, not being able at the present time to realise his resources.

Madame D——, of T——. Husband killed; three houses burnt with the pharmacy. Took refuge with a servant in the dwelling of a cousin who had left for Nice before the war. Had 2000 fr. in ready cash when she departed from T——. Was obliged to live ten days at B—— with her husband suffering agonies. Had to pay after the death of the latter the expenses of living, nursing and attention, and the funeral expenses. Was obliged to borrow from one of her parents at B——, to-day himself deprived of resources, the money which served to provide the food of M. D—— and his servant in the borrowed dwelling which they occupy. Life of privation. Rarely eats meat. Has only one outfit of mourning bought at the commencement of her widowhood. Merits assistance which will be well bestowed. The Committee to grant 700 fr.

M. P. V. M——, of T——. Now at M—— and at S—— alternatively. The pharmacy and druggist's business completely burnt out. Family responsibilities: wife, five sons, and servant. The man who has suffered this loss is 51 years old, has personal resources which the war has much encroached upon. The Committee has decided to make a further inquiry to learn if the need for urgent intervention is corroborated.

All the recommendations of M. Laruelle and M. Breugelmans were agreed to.

The 50 cases of medical material, despatched last December by the Central British Committee, were found to have been of use to the medical men who were able to distribute them gratuitously to their poorer clients; they have been used exclusively in this way.

There was discussion at the séance of April 15th, and again on April 22nd, as to the most expeditious way of allocating the relief, and it was decided to rely on the reports of the delegates. At the séance of April 29th it was agreed to pay monthly subsidies to those who cannot support themselves, even if they have been relieved before.

THE RESPONSIBILITY OF GREAT BRITAIN TOWARDS BELGIUM.

A letter having reached the Central Committee from Dr. Riddle Goffe, of New York, through which it was clear that the attitude of the British Government in respect of its monthly subsidies to the American Commission for Relief in Belgium was misunderstood in the United States, the questions raised by Dr. Goffe were submitted to the British Foreign Office, from whom the following reply was received. It has been decided to publish the reply of the Foreign Office, as from certain references to the situation in American newspapers and publications it is evident that there is still a complete misunderstanding of what occurred, and this might act to the prejudice of any funds being raised in the United States.

Foreign Office, April 26th, 1915.

SIR,—With reference to your letter of the 21st instant, enclosing a copy of a letter from Dr. J. Riddle Goffe regarding the question of Belgian relief, I am directed by Secretary Sir E. Grey to inform you that your correspondent appears to allude to the following facts.

The work of the American Commission for Relief in Belgium consists of two departments—the Benevolent Department, which is concerned with the furnishing of foodstuffs to the destitute in Belgium, and the Provisioning Department, which is concerned with the purchase and sale of foodstuffs to the rest of the population who are still able to pay. The first department has been financed out of private contributions, except for a grant of £100,000 made by His Majesty's Government in October to start the work. The second department has been financed by the Belgian Government.

Last December the Commission asked His Majesty's Government to make a monthly contribution out of public funds to the Benevolent Department. After prolonged negotiations His Majesty's Government decided that they would not be justified in doing so, as it was found impossible to induce the German Government to abandon their extortionate levies of money on the Belgian population. This department of the Commission's work is, therefore, still financed out of private contributions. But your correspondent does not appear to be aware that out of the total private contributions in money and kind received by the Commission up to the date of their last report (April 17th), while the United States has with great generosity subscribed about £980,000, the British Empire has subscribed about £700,000, and this in addition to the military burdens borne by the Empire, the very large sums subscribed to the maintenance of Belgian refugees, and also the credits placed by His Majesty's Government at the disposal of the Belgian Government, out of which that Government is providing for the work of the Commission's Provisioning Department.

---

[1] See THE LANCET, April 3rd, p. 718, and April 24th, p. 883.

As regards the non-interference by the German authorities with the Commission's imports, it must be pointed out that those authorities are thereby acting in their own interests, since the Commission is relieving them of a clear responsibility which they have refused to assume.

Apart altogether from the assistance consistently given in various ways by His Majesty's Government to the Commission, of which it is rather for the Commission itself than for His Majesty's Government to speak, Sir E. Grey feels it to be only just to private persons in this country and the British Dominions who have so largely subscribed to this work and are probably about to subscribe still more largely, that these facts should be made clear, and he has no objection to a copy of this letter being communicated to Dr. Goffe should you desire to do so.

I am, Sir, yours, &c.,
EYRE A. CROWE.

To Dr. S. Squire Sprigge, THE LANCET Offices, W.C.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, are as follows:—

	£	s.	d.
Southern Branch, B.M.A. (per Dr. Jas. Green, Hon. Sec.) (seventh donation—total, £62 5s. 6d.)—			
Dr. J. P. Watkins ...	1	1	0
Sheffield and District Branch of Fund (per Dr. A. E. Naish (Hon. Sec.) (second donation—total, £350)	100	0	0
Knowle, Bristol, Doctors at (per Dr. H. F. Devis)	3	10	6
North of England Branch of Fund (per Dr. James Don and Mr. A. S. Perceval, Hon. Secs.) (twelfth donation—total, £686 7s.)—			
Dr. S. Vernon Robinson	1	1	0
Further fees for examination of recruits by members of Sunderland Division during 1914—			
Dr. McPherson	14	12	6
Dr. G. E. Welford ...	2	2	6
Dr. G. B. Morgan, jun.	2	17	6
Dr. J. C. Hamilton ...	8	2	6
Dr. G. Murray	7	17	6
Dr. W. K. Russell ...	10	7	6
Dr. J. B. Morton ...	20	2	6
Dr. W. Hunter	16	15	0
Dr. R. Stobo...	12	0	0
Dr. J. Martin	6	17	6
Dr. J. Smith	7	12	6
Dr. J. A. Ross	9	10	0
Dr. W. H. Maling ...	16	10	0
Dr. R. H. Dix	5	7	6
Dr. W. Hay	18	10	0
Dr. S. McNaughton ...	9	7	6
Dr. C. A. Rayne	3	3	0
North-East London Pharmacists' Association, collected by (per Mr. W. A. Scott)—			
Mr. T. F. Tabor	1	15	0
Chemists' Assistants Association (per Mr. E. Thompson)	5	0	0
"Formulæ" (per Mr. A. Chapman)	0	10	0
Mr. A. Chapman	0	13	11
Australasian Pharmaceutical Conference (per the Agent-General)—			
Victoria	50	0	0
South Australia... ...	34	0	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd.

THE NATIONAL PEOPLE'S PALACES ASSOCIATION.—This association, the object of which is to extend to the working classes in industrial districts the comfort and brightness offered by tea and coffee houses and general cafés, has now been registered under the Industrial and Provident Societies Acts for the supply of non-alcoholic refreshments at popular prices in armament works and at "palaces" to be established in suitable localities. Mr. Lloyd George has indicated his approval of the association's aims, while Mr. Bonar Law and Mr. Steel-Maitland are associated with the enterprise. Full information may be obtained upon application to the secretary of the National People's Palaces Association, 1, Albemarle-street, Piccadilly, London, W.

The War.

THE CASUALTY LIST.

THE following names of medical officers appear in the casualty lists published since our last issue:—

Killed: Surgeon Frederick W. Quirk, R.N. (on the *Princess Irene*).

Died of wounds: Captain J. C. Matheson, 5th Australian Medical Corps.

Wounded: Lieutenant C. M. Smith (attached 8th Royal Scots, T.F.), Lieutenant J. P. Mitchell, Captain L. C. Hayes (also gas poisoning), Captain E. U. Russell, Captain T. O. Thompson (attached 18th Hussars), Lieutenant G. D. Maclean, all of R.A.M.C.; Major H. C. de Legh (attached 4th Yorks Regiment), Captain H. B. Cunningham, Captain W. E. F. Tinley (attached R.F.A.), Captain J. Murdoch, all of R.A.M.C., T.F.; Captain L. W. Jeffries, 4th Australian Field Ambulance; Surgeon E. G. Schlesinger, Surgeon W. J. McCracken, both R.N.

Captain Stephen Field, R.A.M.C., who was announced in our issue of May 22nd as having been killed in action, died at the Prisoners' Camp, Wittenberg, Saxony, which is one of the camps reported as infected with typhus fever.

DEATHS AMONG THE SONS OF MEDICAL MEN.

The following names must be added to the sons of medical men who have fallen in the war: Lieutenant G. G. Hodgson, elder son of Dr. G. Hodgson, of Chertsey; Lieutenant C. G. Harper, eldest son of Dr. J. Harper, of Rosary-gardens, London, S.W.; Lieutenant J. E. B. Miller, only son of Dr. J. E. Miller, of Londonderry; Lieutenant N. C. MacLehose, younger son of Dr. N. M. MacLehose, of Harley-street, London, W.; and Lieutenant R. W. H. Empson, elder son of Dr. J. Empson, of Milborne Port, Somerset.

THE HONOURS LIST.

The list of honours published on the birthday of King George has close reference to the war, most of the recipients being, as might have been expected, engaged in one way or another in leading the national energies in the great struggle. Medicine is but sparsely represented among these leaders, for enormously valuable to the cause as medicine is, in personnel its numbers are small; the fact that but few medical names appear in the list indicates that in every branch of military activity special services have to be recognised.

We congratulate the following:—Surgeon-General T. M. Corker is appointed C.B.; Dr. A. W. G. Bagshawe, director of the Tropical Diseases Bureau, is appointed C.M.G.—the value to our army of the organised study of tropical diseases has been very great; Major E. J. O'Neill (New Zealand Medical Corps) and Captain A. G. Butler (Australian Army Medical Corps) receive the D.S.O.; Lieutenant-Colonel C. C. S. Barry, I.M.S., is appointed C.I.E.; Lady Lukis, the wife of the Director-General of the Indian Medical Service, and Lieutenant-Colonel T. F. Pedley (Rangoon Port Defence Volunteers) receive the Kaisar-i-Hind medal; and Dr. J. E. A. Ferguson is appointed I.S.O.

We note elsewhere the knighthoods bestowed upon Sir James Mackenzie and Sir Frederick Needham, as being civilian honours,

THE SOUTH AFRICAN AMBULANCE HOSPITAL AT CANNES.

We have received from M. Réné Juta, the Secretary of this hospital, an account of the first and only South African unit in Europe, which is also probably the largest British hospital working for the French Service de Santé. It comprises 3 surgeons, 9 sisters, 10 nurses, 6 dressers, 1 accountant, 1 secretary, 4 motor drivers. It has 200 beds and 3 motor ambulances, all equipped and subscribed for in South Africa by private and public funds for work in Europe, in spite of the fact that the Union has recently had rebellion on its hands and is carrying on its own arduous campaign in German South-West Africa. The ambulance was accepted by the French Service de Santé, and its personnel were asked to equip and organise a base hospital at the Beau Rivage, Cannes. The hospital has been commended by the French Government, and is admirably equipped. The wounded come almost direct from the trenches of Verdun and the Argonne.

There are two committees, one in Cape Town with the Chief Justice as chairman, the other in London with Lord Gladstone as chairman, Lord Islington, honorary treasurer, and Mr. Wilson Fox (of the Chartered Company) as secretary. There is also a ladies' committee in London, of which Mrs. Lewis Harcourt is President. A bacteriological laboratory and X ray apparatus and outfit have been given to the hospital by the London committee. In addition the hospital has a dental surgery under a fully qualified dental surgeon. At the time of writing 193 patients have been admitted, with 2 deaths, while 61 patients have been sent home healed.

The South African Ambulance Hospital at Cannes.

CANADIAN MEDICAL MEN AND THE WAR.

One of our Canadian correspondents writes: "Medical men in Canada who are eager and anxious to go to the front read from time to time in the columns of THE LANCET of the 'dearth of medical officers' and of the dearth of medical men in the home country. They wonder how it is, when they have long since proffered their services, that it seems impossible to secure a commission, although many of them have taken emergency training to qualify them in some measure for usefulness. Up to April 1st, it has been stated, Canada had some 300 medical men in England or in France, either with the armies, in hospital service, or with the navy. Recently the University of Toronto General Hospital has gone abroad with some 40 to 50 medical men; McGill University, Montreal, has sent a similar or larger number. Queen's University, Kingston, and Laval University, Montreal and Quebec, have sent, or are sending their hospitals abroad. Lately Vancouver has offered to equip a hospital of some 1040 beds; Peterboro, Ont., one of 200 beds; Lambton County, Ontario, one of 200 beds. The Ontario Medical Council, through one of its members, Dr. Edmund E. King, Toronto, has selected some 50 or 60 medical men for the War Office. Thirty men have volunteered for service in Serbia. With all this splendid offering from the medical profession in Canada there are said to be hundreds on the waiting lists who are urgently desirous of work in any medical capacity. The provincial medical councils of Canada could yet supply several hundred men."

ITALY AND THE WAR: "THE PLEBISCITE OF THE PROFESSIONS."

From the Alps to Etna, every seat of learning and source of professional qualification (writes an Italian correspondent) has demonstrated, by word and deed, its whole-hearted sympathy with the Salandra-Sonnino administration in the policy which has placed the Third Italy by the side of the Triple Entente in the war against the Central Powers. Of the 21 universities which Italy numbers there is not one which has not declared its solidarity with the movement now in progress—mainly on the Venetian frontier and on the Adriatic seaboard—to complete the country's territorial integrity and to make meaningless the phrase "Italia Irredenta" (unredeemed Italy) and the agitation it has since 1866 inspired and justified. The last few weeks have witnessed what the leading Italian journals call "Il Plebiscito dei Professori"—a veritable plebiscite of the academic and professional interest throughout the kingdom—a "demonstration" which has reinforced, with signal unanimity and power, the various other interests, agricultural, industrial, and commercial, in baffling the Germano-Austrian diplomacy and in sending Italy, by the rupture of the ill-starred Triple Alliance, to the support of England, France, and Russia, in their antagonism to the policy whose watchword is "Deutschland über Alles."

Every Senatus Academicus has, collectively, subscribed to the manifesto organised to aid and abet the Government in its programme of intervention, and the names of the professoriate, published in full, have been for days past a feature in the leading journals. Conspicuous among these appear the signatures of the medical faculty in every school, metropolitan and provincial, and not a few of the signatories, when of the required age, have volunteered to serve at the front not only in ambulance work but, if need be, in the fighting line itself. There could not be a more significant proof of the patriotic spirit thus evoked than the correspondence that has passed between the organisers of the manifesto and such veterans in clinical and consultant practice as the leading members of the faculty at Naples and Rome, at Pisa and Bologna; and of these it may suffice to quote the letter of the illustrious pathologist of the last-named school, Professor Augusto Murri, addressed to Colonel Bernardi, director of the "Servizi Sanitari" of the local army corps.

> My Honoured Colleague,—I address myself to you, in this confidential strain, to assure you, with perfect frankness, that all of us of the Clinica Medica feel it our duty to coöperate, in whatever way seems best, in the defence of Italy if she should be called upon to intervene in this war. While all my assistants are already under statutory obligation so to intervene, I have only one such call, and that is my conscience. Be it the privilege or the misfortune attaching to age, be it what you will, I must needs obey the command of conscience; and, therefore, to you my honoured colleague—to you who direct the sanitary service of our army corps—I say that, if I am not wholly without use in the service alluded to, you may count upon me to undertake, with implicit acquiescence, any duty whatever you may impose upon me—not in the higher sphere to which your kindly appreciation might tempt you to call me, but in any other, however humble. For me, as for many others, the dignity of the post is not to be measured by the nature of the work assigned to it, but by the love of our dear country, which is now claiming only that respect for her rights hitherto denied her by an unscrupulous oppressor."

This characteristic letter was addressed, as long ago as March 10th, to Colonel Bernardi, since deceased, and has been made available for publication by the courtesy of his widow. Time would fail me to quote, and the space at your disposal to publish, the volunteered undertakings of clinical teachers and consultants, inspired by equal patriotism and couched in similar language to that of the celebrated pathologist of Bologna, "the Mother of Universities." One remark, however, may be made, and it is this: that a movement so animated and so organised as that of the "Plebiscite of Italy's Professors" in this crisis of their country's destiny may not indeed command success, but must assuredly deserve it.

THE TOURING CLUB OF FRANCE AND THE WAR.—The approach of what used to be the holiday season prompts the inquiry, What has become of the touring clubs? Foremost among these, by reason of its influence, the number of its members, and the excellent service it has rendered, not least conspicuously in imposing better sanitary conditions in hotels, is the Touring Club of France. When war broke out this club had under its inspection all over Europe hotels at which members were certain of cleanliness, moderate charges, and easy redress for any legitimate grievance on reference to the club. But the war has changed all this, for many of the hotels are now converted into hospitals. So vast an organisation, however, could not remain idle, making no use of the magnificent premises secured by it for its headquarters—viz., the mansion in the Avenue de la Grande Armée once inhabited by the Humbert family, where the safe that was supposed to contain the fabulous fortune of the mythical Crawford family was kept. At this time last year this building was the centre for organising touring and exploring expeditions in all directions. Now the tourists are for the most part fighting at the front, so the Touring Club has been converted into an organisation for contributing to the health and convenience of those in the fighting line.

With the sanction and help of the Minister of War it has created a committee, known as l'Œuvre du Soldat au Front, to help soldiers at the front. Its object is to supply the soldier with necessary things which he does not obtain from the Ordnance Department. The magnificent drawing-rooms of Madame Humbert's mansion are now converted into workshops, and the Touring Club of France has succeeded in turning out no fewer than 2500 parcels a day, each containing from 25 to 30 articles. These comprise things useful in maintaining the cleanliness and the warmth of the soldier, and thus conducing to his health, things which, nevertheless, the war administration does not provide. For instance, there is a watertight hood that protects the back of the neck like a sou'-wester. There are also warm socks, woollen mittens, towels, soap, combs, hair and tooth brushes, grease for the feet, an ampoule of iodine, thread, buttons, safety pins, and a very ingenious over-shoe. This last can be made easily with any little bit of carpet or rug. It slips over the shoe to keep the feet warm while sleeping or standing still in the trenches. Then there is a powder or an ointment that is very successful in keeping away vermin. The other objects are of the nature of comforts, or even luxuries, that bear no direct relation to the question of health preservation, such as mirrors, flint tinder-boxes, candles, tobacco pouches, cigarette papers, postcards, pencils, bootlaces, jam, books, and such like.

The subscriptions paid by tourists who no longer go out touring were obviously insufficient to provide enough parcels of this description, consequently the Touring Club conceived the ingenious idea of organising throughout France the "Day of the 75." Millions of postcards, medals, and little flags were prepared recalling the great service rendered by the famous gun. These little trinkets, none of them the size of half a crown, weighed *en bloc* nearly 20 tons. They were sold for a penny and upwards and brought in no less than 5,200,000 francs. What this means may be judged by the fact that a million francs in silver 50-centime pieces weigh five tons and in 10-centime copper pieces a hundred tons. Special arrangements had to be made with the banks to deal with the huge amount of small coin thus paid for mementoes of the 75 gun. The £208,000 which an army of 50,000 ladies realised by selling 22,000,000 mementoes have greatly helped to increase the comforts for the soldiers. But there is more money yet to come in, for the receipts from the colonies and distant places are not yet to hand, so that the tourists of France have rendered yeoman service for our common cause.

The war has not, however, compelled the Touring Club entirely to neglect the interests of the tourists. The upkeep of roads, which was a part of its business, has proved of great service for military purposes, as well as for the comfort and safety of tourists. Further, the club has begun a campaign to spread the knowledge as to where and how, without traversing the enemy's lines, advantages such as were formerly enjoyed at Homburg, Wiesbaden, Marienbad, Karlsbad, and similar places, can now be obtained. An extensive correspondence also, including many letters from England, consisting of inquiries about the French health resorts, has been conducted. It is quite certain that no English families will go this summer to either German or Austrian baths or spas. With the exception of those situated in the Vosges and the Ardennes, the resorts of France generally are available. The Touring Club urges that this affords an excellent opportunity for setting forth the superiority as regards politeness and attention that France can offer such visitors.

BELGIAN RED CROSS: WAR EXHIBITION, 1915.—A war exhibition to assist the funds of the Belgian Red Cross Anglo-Belgian Committee, of which the Queen of the Belgians is patroness, is announced to be open from June to October at the Prince's Skating Club, Knightsbridge, S.W. A 13,700 sq. ft. mural panoramic representation of Belgium will portray the beauties of Brussels, Antwerp, Bruges, Ghent, Liége, Namur, and the Valley of the Meuse, including Dinant, Louvain, Malines, Ypres, and Visé. The exhibition includes seven sections, forming a comprehensive war exhibition. Section 1: Trophies of war from the more important battle-grounds. Section 2: Armament and ammunition in the making. Section 3: Red Cross work, hospital and nursing. Section 4: Science and industry as applied to war, including the latest scientific instruments used in connexion with war. Section 5: Food and hygiene. Foodstuffs of every description for War Office requirements, for invalids, wounded, and convalescents, also hygienic preparations and apparatus. Section 6: Equipment, showing every equipment necessity of officers and men, nursing equipment for hospital and field service, working exhibits, lectures, and demonstrations. Section 7: Maritime and aerial section, comprising the latest inventions in naval and aerial warfare. Season tickets are being issued at £1 1*s.* each, carrying the privilege of admitting a different friend at each visit. Assistance of every kind will be welcomed by the honorary organising secretary, War Exhibition, London Chamber of Commerce, 97, Cannon-street, London, E.C.

EDINBURGH UNIVERSITY OFFICERS TRAINING CORPS MEDICAL DUTY.—On May 29th the cadets of the medical unit of Edinburgh University Officers Training Corps were inspected by Major Gray, R.A.M.C., at Kingston Grange, where the unit had fitted up a field ambulance. After a careful inspection of the field hospital arrangements and the cadets in various manœuvres, the inspecting officer addressed them, and expressed his satisfaction with what he had seen. Speaking of the value of such a unit, he said some people thought there was no good having the Officers Training Corps during war, but there was no greater possible mistake, as the essential qualification for Royal Army Medical Corps officers, apart from the medical one, was military training. Had there been no such Officers Training Corps, the Army Medical Corps at the outbreak of war would have been in difficulties. Some who had previous training rather grumbled at having to train recruits at home, yet they had done more useful work than going straight out, and they would get their chance now. Students felt that they were being blamed for hanging back and not joining a combatant unit. Nothing was more foolish. Combatant officers could be trained in a few months—for example, at Sandhurst in three—but it took five years to train a Royal Army Medical Corps officer, and should the war last a long period there would be a shortage of doctors. It was their duty to stick to their studies, taking the necessary military training in such a unit as this; ultimately they should join the Royal Army Medical Corps.

WOUNDED ALLIES RELIEF COMMITTEE.—As Dr. R. Fleming Jones, whose appointment we recorded in THE LANCET of May 8th, has been prevented from going to Serbia, the Wounded Allies Relief Committee has appointed instead Colonel Joseph A'Hearne, who has for many years been associated with the Government Medical Service of Queensland.

The committee has also appointed as medical head of its typhus hospital unit (200 beds) about to proceed to Montenegro, Dr. Gerard Carré, formerly medical officer to the Uganda Relief Expedition, and senior medical officer to the Fashoda Expedition. The medical staff will also include Dr. Isabel Ormiston, Dr. C. B. Slater, and Dr. Lillias Hamilton. Miss Elkington is matron and there are 14 nurses and one male nurse attendant. Another matron with five nurses will follow later.

SCOTTISH COMMAND: MEDICAL SERVICES.—Colonel J. D. Mackintosh, Assistant Director of Medical Services 2/1st Lowland Division, in addition to other duties, has been appointed to supervise the administration and organisation of all military, war, and Territorial general hospitals in the Glasgow area. Major H. A. Leebody, from Officer Commanding 2/3rd Lowland Field Ambulance, to be Deputy Assistant Director of Medical Services, Scottish Command, dated March 5th, 1915.

NEW MILITARY HOSPITALS.—The military authorities are taking over for a military hospital the Western District Hospital, Possil-road, Glasgow, which is a modern and well-equipped institution with accommodation for 250.—The Lanarkshire Red Cross Society, through its President, the Duchess of Hamilton, has been authorised by the War Office to take over for a hospital the new school buildings at Gateside, Cambuslang.—The Devonport Workhouse has been taken over by the War Office and will be converted into a military hospital for wounded soldiers. The infirmary, which contains 150 beds, will be used immediately, and in about three weeks it is expected that the workhouse will be fitted up for the accommodation of about 400 additional patients.

RURAL MEDICAL RELIEF IN SERBIA.—Owing to the heavy death-rate from typhus fever among the Serbian medical profession and the absorption of the remainder in military and fever hospitals in towns, the rural population is entirely deprived of medical aid. Mrs. St. Clair Stobart describes in the *Morning Post* of May 25th how in an effort to aid them a hospital tent was planted on the road between Kragujevatz and Belgrade, with a notice in Serbian that medicine and advice would be given gratis to those who attended and brought their own bottles. The success was instantaneous, and over 500 patients are reported as having been treated during the first week, having trudged from their villages even so far as 50 miles away. The authorities have now given permission for a series of these roadside dispensaries, along the main road, administered from the Women's Tent Hospital, to be established, each such unit to consist of a woman doctor, two nurses, an interpreter, a chauffeur, and a handyman. The staff will live in tents and attend to their own sanitation, which will have an educative effect also on the peasantry. The expenses of outfit and three months' maintenance are about £1000 for each unit, and it is desired to start six units as early as possible. Mrs. Stobart says: "From the humane point of view alone it is inconceivable that money could be better spent than upon these brave and patient peasants who are suffering from a foe against whom they have no weapons of defence. Villages are being decimated, whole families blotted out, and horrors unspeakable are being endured by these peasants without complaint, because they take it as their share of the sacrifices which have to be made by the whole nation in the cause of Freedom. But it is a heavy price to pay, and it is impossible to watch it being paid without attempting to lessen even to a small degree the horrible toll of suffering." Donations marked for the Stobart Dispensaries will be gladly received by the treasurer of the Serbian Relief Fund, 55, Berners-street, London, W.

Dr. Fabian Ware and Dr. Oswald Kelly, chief medical officers of mobile units of the British Red Cross serving with the French Army, have been mentioned in French Army orders for conspicuous devotion to duty.

Scottish Women's First Aid Corps.—The annual meeting of the Scottish Women's First Aid Corps was held in the Synod Hall, Edinburgh, on May 28th, Mrs. Maxtone Graham, the corps commandant, presiding. Miss M. E. Macmillan, honorary secretary, read the annual report, which stated that the corps was started six years ago in order to train women to be in readiness to render help to the wounded in the event of war. The scheme was justified, said the report, by the large number of competent trained women who were ready to serve when the war broke out. Since April, 1914, 219 new members had joined, and the corps now numbered 356, and, in addition, about 300 non-members had taken advantage of their classes. A house lent by Mr. Frank Deas in Magdala-place had been equipped and furnished by members of the corps as a special corps hospital. It was now occupied by wounded soldiers, was recognised by the Scottish Command, and received the capitation grant. Mrs. Graham referred to the progress made by the corps during the year, and remarked that their hospital was a kind of visible outcome of what they had been doing. The honour of the corps was in the hands of the members, who must do everything they could to make the hospital a success. They had been getting soldier patients from the City Hospital and from the Deaconess Hospital, and she was sure that so long as they kept the hospital open it would never be empty. They got the capitation grant from the Government, but that was not sufficient to keep the hospital going, and they would require to raise more funds.

Kitchener's Indian Hospital.—Tents to accommodate 500 more beds are being put up to augment the accommodation of this hospital, which was fully described in The Lancet of April 3rd. The staff consists of 37 officers of the Indian Medical Service, mostly from three Indian general hospitals, and some had to give up lucrative appointments to serve in Kitchener's Hospital. There are also 15 Anglo-Indian assistant surgeons, 30 native sub-assistant surgeons, 150 sepoy ward orderlies, 100 native followers, and 75 British orderlies of the R.A.M.C.

Collaboration in Operative Surgery.—A medical correspondent, signing himself "Observer," writes that he was recently an eye-witness of operations at the Royal Military Hospital, Devonport, illustrating the possibility of collaboration in surgical operations. The operations, he says, were for the radical cure of bilateral inguinal herniæ by Bassini's method. Two operators took part, one on either side. The initial incisions were simultaneous. Both operations, though varied in technique, proceeded *pari passu;* and the last skin suture in each was inserted simultaneously to a second. The only point for discussion (that of dressings or no dressings) was harmoniously compromised, and the patient is doing well, the period of anæsthesia and the shock of operation being both reduced by half. Such an illustration speaks highly for surgical collaboration. Here skill met skill, not as "Greek meets Greek," but as allies in a hallowed cause. No small credit, too, is due to the sister who supplied both operators synchronously and speedily with their varied armamentarium.

Alleged Robberies of the Wounded by Medical Orderlies.—There has been not a little direct accusation levelled in various newspapers against medical orderlies of petty thieving practised on the wounded during transport. One very specific instance in the *Times* of May 28th has drawn forth from Colonel P. Broome Giles, of the City of London Branch of the Red Cross Society, a very trenchant and just reply. After referring to the difficulties that lead to defective packing of kits upon ambulances, illustrated by a singular instance, he calls attention to the *primâ facie* unlikelihood of the charge from the general position and character of those engaged in the transport work, and concludes: "If your correspondent will furnish me with (1) the date; (2) the hour; (3) the hospital the officer was taken to, I can verify from the duty roll those she implicates, and will give her every facility to make an exhaustive inquiry, after which she can either publicly substantiate her accusation or apologise." That many articles are lost during transport is highly probable, and it is difficult to conceive how it could be otherwise when all attendant circumstances are taken into consideration, so that it is quite gratuitous to propound as the only explanation a highly improbable system of thieving.

Incorporated Soldiers' and Sailors' Help Society.—This society held its annual meeting on May 26th, when the secretary, Major Tudor Craig, said that over 23,000 beds had been presented to convalescent homes by the members of the society since the war began. The Princess Christian Home at Brookwood was also to be turned into a convalescent home, and the accommodation at the Naval Hospital had been increased to 128 beds. Princess Christian said that the necessary funds had been offered by a friend through the Queen and herself, and she thought that the extension would remain permanently at the hospital. The secretary continued that a fund in memory of Lord Roberts had been instituted to enable the partially disabled to be dealt with. The Cordwainers' Company would give disabled men 42 weeks' training in cobbling, the society making them meanwhile an allowance. The National Fund had helped with a grant of £35,000.

A Military Chamber of Horrors.—The Royal United Service Institution have expressed approval of a suggestion of Dr. Raymond Crawfurd that a "chamber of horrors" should be established in the museum of the institution for the display of a collection of objects testifying to the commission of atrocities in warfare, such as German military proclamations, letters and diaries ordering or recording atrocities, the Botha correspondence on the infection and poisoning of wells, German gas apparatus, incendiary pastilles, and the like. The War Office is considering the matter.

Sir George Newman, principal medical officer of the Board of Education, has been appointed on the Central Control Board (Liquor Traffic) created by the Government to deal with the drink problem in relation to munitions, transport, and camp areas. The address of the Board is 76, Strand, London, W.C.

Medical News.

University of London.—At the third M.B., B.S. Examination for internal and external students, held recently, the following candidates were successful:—

Lilian Annie Clark and *Dora Challis Colebrook (honours), London (Royal Free Hospital) School of Medicine for Women; †Clement Cooke, St. Bartholomew's Hospital (honours); Herbert Davies, University College Hospital; Robert Hood Fleming, B.Sc., Middlesex Hospital; Norah Hamill and Mary Emmeline Joll, London (Royal Free Hospital) School of Medicine for Women; William Edward Kingdon, University College Hospital; Olive Gertrude Mary Langmead, London (Royal Free Hospital) School of Medicine for Women; Stylianos George Papadopoulos, St. Bartholomew's Hospital; George Henry Roberts, St. Thomas's Hospital; Gabriel Francis Rodrigues, University College Hospital; Farid Henein Abdel Sayed, St. Mary's Hospital; Hilda Mary Scarborough, London (Royal Free Hospital) School of Medicine for Women; John Frank Herbert Stallman, Guy's Hospital; and Katharine Ada Waring, London (Royal Free Hospital) School of Medicine for Women.

* Distinguished in Midwifery and Diseases of Women.

† Distinguished in Medicine.

Central Midwives Board.—Special meetings of the Central Midwives Board were held at Caxton House, Westminster, on May 26th and 27th, Sir Francis H. Champneys being in the chair. A number of midwives were struck off the roll, the following charges amongst others having been brought forward: Not being scrupulously clean in every way as required by Rule E.1; that when attending patients the midwife did not take with her the appliances or antiseptics required by Rule E.2, and consequently was unable to comply with the provisions of Rules E.3 and 7; not taking and recording the pulse and temperature of patients as required by Rule E.13; the midwife employing an uncertified person to visit the patient as her substitute in contravention of Section 1 (4) of the Midwives Act, 1902. Neglecting without reasonable cause to attend a patient on the day of the confinement in spite of repeated messages, and not arriving until after the delivery had taken place; that notwithstanding instruction by the inspector of midwives the midwife did not make use of a clinical thermometer, nor did she take the pulse of her patients, and consequently did not comply with Rule E.13.

That in contravention of Section 10 of the Midwives Act, 1902, a midwife practised as a midwife in 1915 without having notified the local supervising authority of her intention to do so. Not always attending patients for a period of ten days following labour, as required by Rule E.11; not keeping a register of cases as required by Rule E.23; when attending patients the midwife did not wear a clean dress of washable material, as required by Rule E.1, and that in cases where the advice of a registered medical practitioner had been sought she neglected to notify the local supervising authority thereof, as required by Rule E. 21 (1).—An application from the examiners of the Manchester Centre asking the Board to arrange for examinations to be held six times a year alternately at Manchester and Liverpool was granted. The Board decided that the Brighton Hospital for Women should be reinstated upon the list of institutions at which pupils may be trained on the annual approval by the Board of their lecturing staff and training midwife. Letters were considered from the medical officer of health of Sheffield and from the county medical officer of health of Lancashire inquiring whether a rupture of the perineum is to be considered "serious" within the meaning of Rule E. 20 (3) in every case where stitching is required. The Board decided that any case of a ruptured perineum which required stitching was a case of "serious rupture" within the meaning of the rule.

THE TYRONE MEDICAL COMMITTEE.—At a meeting of medical men, held in Dungannon, Dr. E. C. Thompson (Omagh), President of Tyrone Medical Committee, in the chair, it was decided to write to those Tyrone doctors who had accepted positions as "half-time certifiers" under the Insurance Act, requesting them to fulfil their pledges to the Tyrone Medical Committee and resign their positions, and stating that, in case of refusal, upon the first occasion on which an offender visited the patient of another medical practitioner an application would be made to his College to have his licence as a practitioner cancelled. It was also decided that the medical officers of the various Poor-law unions should press for four weeks' vacation each year and that the locum-tenents be paid £4 4*s.* per week, and each medical practitioner was requested not to accept less. It having been mentioned that Dr. E. C. Thompson, surgeon to the Tyrone County Infirmary, Omagh, had been removed from the position as medical adviser for co. Tyrone under the Employers' Liability Act, which he had held since 1896, and another doctor appointed, it was decided to ask for an explanation from those in authority why Dr. Thompson without notice or explanation had been removed from the post.

MIDDLESEX HOSPITAL.—Presiding over the quarterly meeting of the Court of Governors of the Middlesex Hospital on May 27th, Sir Henry Morris referred to the valuable results which were expected from the electrocardiograph department of the hospital. The report stated that since the beginning of the war 301 soldiers of the Expeditionary Force had been treated in the hospital, while at the branch institution at Clacton-on-Sea 1432 wounded soldiers had been treated.

THE MONTESSORI SYSTEM. — Speaking at a meeting of the Montessori Society, held at University College on May 22nd, Mr. C. W. Kimmins, D.Sc., Chief Inspector of Education to the London County Council, said that children who had been educated under the Montessori system were about a year in advance of others who had received ordinary methods of instruction. The children were more resourceful and easily overcame the difficulties of unseen work. Dr. Kimmins warned his audience against introducing new methods without adequate preparation.

THE ROYAL SOCIETY.—The meetings of the Royal Society previously announced for June 10th and 24th will not be held.

THE death is announced of Mr. J. P. Martin, L.R.C.P., L.R.C.S. Irel., the medical officer of No. 1 West District, Liverpool. Mr. Martin, who was greatly endeared to the poor of the Great Mersey-street district, where he lived, had a wide circle of friends and was a generous supporter of Liverpool charities.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BAKER, LILY, F.R.C.S. Irel., M.B., Ch.B. Irel., has been appointed a temporary Demonstrator in Obstetrics and recognised Teacher in Ophthalmology, Laryngology, and Otology at the Bristol University.

BARNES, HELEN PATRICIA, M.B., B.S. Lond., has been appointed Resident Obstetric Officer and Ophthalmic House Surgeon at the Bristol Royal Infirmary.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL FEES, ETC., IN THE SIXTEENTH AND SEVENTEENTH CENTURIES.

AMONGST the historical documents belonging to the Duke of Rutland preserved at Belvoir Castle are a number of household account books of various dates ranging from the year 1522 to the year 1700. These are of much interest as illustrating the stately housekeeping of a wealthy noble family in the sixteenth and seventeenth centuries. The accounts throw light on local and family history, social customs, the manner of living, food, drink, the history of prices, trade, amusements, costume, and innumerable other subjects. Entries of payments for tobacco and pipes, the price of the former sometimes running very high, show how esteemed the custom of smoking was among the nobility. The accounts also indicate that in 1670 tea was regarded as a necessary part of the Earl of Rutland's equipment for a journey in England. On May 6th of that year, for instance, we find a charge of 8*d.* "for a box of tin to keepe his Lordshipp tea in coole for his journey," and on Nov. 20th of the same year there is the entry, "for ½ a pound of tea for his Lordshipp, 10*s.*" Subjoined are a few examples of payments recorded to physicians and apothecaries and other items of expenditure of direct or remote medical interest:—

1528.—Payde, be my Lorde's comaundement, to Doctor Freman, fysicion, xl*s.*

1530.—Item, to Doctor Freman, fusician, x*s.*—To Doctor Freman, fusician, for his paynes with my Lorde Ros, xx*s.* Item, to Doctor Bartlott, by my Lorde's commaundement, vij*s.* vj*d.*—Item, to Peerson the poticary for divers restoretyffes, vij*s.* iiij*d.*

1532.—Item, geven in rewarde to the myddewif and norys at the christenynge of Master Hervie's childe, xx*s.*

1533.—Item in reward, the xij day of *Julii*, to Roger Smyth, poticarye, for his payne takyn with my Lord in his fevir, vij*li.* xiij*s.* iiij*d.*; to him for such stuff as he spent abowt my Lord in the tyme of his sekenesse, xxxij*s.* x*d.*—Item in reward at the same tyme to Doctor Bartlet, xxx*s.*—Item in reward to Doctor Freman the same tyme, xiij*s.* iiij*d.*—Item to a woman phicisian at Bingeham in the Vale, iij*s.* vj*d.*—Item to Roger Smyth, poticary, for my doughter Anne, iij*s.* iiij*d.*

1536.—Item to Doctor Clement for lokyng to my Lorde Roos when he was seke at Endfyld, xxx*s.*—Item to the same doctor at another tyme at Yorke Place, x*s.*

1537.—Item in reward to Master John the poticary for ij glasses of oyle of almons and for a medicen for my Lorde's childern for the wormes at ij tymes, x*s.* x*d.*

1540.—Paide in reward to Doctor Bill commyng to my Lorde at Halywel, xx*s.*—Item payd to Doctor Edwardes for his reward, beyng with my Lord Roos at Croxton in his sekeness, and for his costes goyng to Cambrige for ix days at vj*s.* viij*d.* the day, iij*li.*

1541.—Item, the xxvijth day of February, to Mr. Leveret, the phesicion, for that he came to my Lady then and tarried at Belvoier iij days, x*s.*—Item, gyven in rewarde to Mr. Edwardes, phisicion, of Newarke, for his comyng to se Maistres Margaret Paston when she was seke, v*s.*—Item, gyven in reward to Mr. Leverett for mynystryng medecyns to my Lord Roose when he was seke, x*s.*; and for the like mynystryng to Maistres Margaret Paston in her sekenes, xxii*s.* vj*d.*—Item, payd for a pynte of aquawyte, xij*d.*

1542.—Gevyn to Doctor Augustyne at dyverse tymes (over and beside iiij*li.* x*s.* in the price of a gowne of damask) lxxv*s.*—Gevyn to Doctor Buttes, xxij*s.* vj*d.*—Gevyn to Doctor Nicholas at dyverse tymes, viij*li.* x*s.* x*d.* Gevyn to Doctor Crome at dyverse tymes (over and beside xj yardes of damask for a gowne, price iiij*li.* x*s.*), lxxvij*s.* xj*d.*—Gevyn to Docter Bill at ij tymes, xl*s.*—Gevyn to Mr. Oliff, the Kinge's surgian, at diverse tymes (over and beside xj yardes of damask for a gowne, price iiij*li.* ij*s.* vj*d.*) vij*li.* xiiij*s.* vj*d.*—Paid by Anthony Digby for ypocras when my Lorde was syke, vj*s.* viij*d.*

A NURSE'S EXPERIENCES.

THE *St. Mary's Hospital Gazette* for May contains a very interesting and instructive account of the German conduct towards British Red Cross nurses and doctors in Belgium, which deserves a wide circulation, for it should act as a strong incentive to recruiting among men of manliness and chivalry. Nurse Hilda Speak, after briefly describing the operations of the English ambulances in Brussels, tells how for a month after the coming of the Germans to the city they attended on English wounded prisoners there :—

"One day a German officer ordered all there to be locked up in a waiting-room, saying that they were acting as spies. They were thoroughly searched and kept there for thirty-six hours, until the American Consul interfered. A few days after an order was issued to the effect that all the English nurses and doctors were to go out of Brussels or they would be taken as spies. As there was no possible chance of our getting out of Brussels without help, the Germans were asked to find some means of seeing us away. After considering for some days we were told to be ready to leave on October 6th. ......At last we got into the train. In each compartment there were German soldiers. There were three other nurses in my compartment and two soldiers of the roughest and most objectionable type. They smoked and ate continuously until we reached Cologne, and would insist on having the windows closed. The carriages were the worst I have ever seen—hard wood seats and backs and very, very dirty. There were also soldiers riding on the top of the carriage. It took twenty-eight hours to reach Cologne; in ordinary times it takes four hours. The train crawled, and we seemed to stop every few minutes. During the journey through Belgian territory we noticed the awful devastation all along the line, many towns and villages containing only a roofless lot of ruins. Louvain appeared to be practically wiped out. Imagination can never picture the terrible ruin done to Belgium. At Stolberg, a small station just before Cologne, we were very roughly told to get out of the train. There I saw a young German officer take two of our doctors by the shoulder and throw them across the platform. At this point I was more alarmed than I had been since entering Brussels. Our luggage was all turned out on the platform and the soldiers searched it. All knives and forks were taken, surgical instruments, and even a nurse's fountain pen. After looking through our papers and a great deal of consultation, we were told to get into the train again by the soldiers, and we started for Cologne. I think if some of our young men in England had witnessed the treatment of the British Red Cross at this station it would help them to make up their minds as to where their duty to their country lies. There were twenty doctors; they could not retaliate, their only thought and care being for the hundred and twenty-four nurses who were in their charge in the country of the enemy. At Cologne we got our first meal, and were treated quite reasonably. ...... We still had a guard with us, and arrived at Münster at 7 A.M. on Oct. 8th, where we were evidently expected, and given breakfast at the station. It appeared to be a camp station: there were a great many soldiers round about. They gave us basins of coffee, sausage and bread. We washed our hands and faces under a pump, and felt much better for the food and wash. After an hour's wait we entered the train again. ...... We continued the journey, and that night had no light in the carriages. We arrived at Hamburg at 1 A.M. on Oct. 9th, but were not well treated there. We left the train for ten minutes, guarded by soldiers each side to a refreshment room, but we were waited on very badly, the food being practically thrown at us. ...... After travelling four days and three nights we arrived on the Danish frontier, and there we stopped for the German guard to leave the train. No one except those who have experienced it can imagine our feelings as we left the Germans behind and knew we were prisoners no longer. Then our destination was Copenhagen, where we were kindly received by the British Consul there. The people were exceedingly kind to us."

A significant sidelight upon the estimate by outsiders of the moral issues of the war is given by Miss Speak in the following grimly dour verse addressed "To the British Surgeons and Nurses Passing Copenhagen on Their Way from Belgium," which in English greeted them from the columns of a Danish newspaper on their arrival in Denmark :—

Silent we bid you welcome,
In silence you answered our greeting—
Because our lips must be closed
And your teeth set against the gale.
Our mouths are mute,
Our minds are open—
We shall greet you farewell in silence.
Sowers of good-will
On fields where hate is sown,
Fare ye well!

LEFT-HANDED SOLDIERS.

AN inquest has been held in London on a left-handed soldier who committed suicide, and there seems to have been a feeling that his left-handedness may have had considerable influence in depressing the man, for in reply to the question put to an officer in the man's battalion as to whether his left-handedness would make him awkward, the officer replied, "We have several who are like that, but we train them in time, and we also teach them to shoot from the left shoulder." Among the reasons assigned for left-handedness (excluding traumatic origin) have been heredity, left or right breast-feeding or carrying, mimicry of other children, functional nervous disease, and idiopathic epilepsy. Other reasons have been suggested, but the etiology is uncertain. The rate of percentage of left-handedness in this country is usually accepted as between 2 and 5 per cent. Among 17,000 school children examined in Berlin 5·15 per cent. of the boys and 2·98 per cent. of the girls were found to be left-handed. Left-handed Hebrews appear to have possessed as a rule more than ordinary skill in warfare, for in one army of 26,700 men, of the "chosen men" of the army, 700 were left-handed, and the context suggests that these were all the inhabitants of one town—Gibeah. Moreover, "every one could sling stones at an hair breadth and not miss" (Judges xx. 16).

WHAT IS A CONSULTANT?

To the Editor of THE LANCET.

SIR,—I am grateful to Dr. A. Charpentier for his letter in your issue of May 22nd. A consultant is sent for to, say, the Langham Hotel by an urgent message. Remembering it may be a case of life and death, would he go? He goes, and finds a case of acute tonsillitis, the patient having just arrived from Yorkshire. The sick man says to the doctor: "I wish you to attend me until I am well, and I will, of course, pay you £3 3*s*. a visit." What is the duty of the consultant?

I am, Sir, yours faithfully,
ENQUIRER.

May 25th, 1915,

ICE.

THE hot weather will doubtless cause an increased demand for ice, especially for the wounded. It has long been a reproach to this country that the only man known usually to keep ice in hot weather is the fishmonger, whose sanitary environment is not always of the highest standard. The initial cost of an ice-safe is prohibitive to many, but practically its cost is soon saved in the value of food preserved and utilised which would otherwise have been lost. It has also been suggested that the milkman might carry ice for sale on his rounds. Ice production is a huge industry in the United States. The American Ice Company with the Knickerbocker Ice Company claim to be the largest manufacturers of ice in the world, and in 1911 there were 2004 ice manufacturing establishments in the United States with a capital of 118 million dollars. Their products were valued at 43 million dollars in 1909, as against 24 million dollars in 1904, and the number of employees was 19,041. This did not include the ice manufactured in breweries, meat, provision, and cold storage warehouses, and other industries that produce it for their own use. If in America ice is used too indiscriminately, in this country its use is too much neglected, and there is room for expansion on the right lines.

THE HOUSE-FLY.

Dr. A. Mearns Fraser, the medical officer of health of Portsmouth, has issued for his health authority a useful two-page leaflet explaining the dangers caused by the house-fly and how these dangers may be prevented. In the last paragraph Dr. Fraser says: "It has been stated that in a certain lunatic asylum one of the tests applied to find out if a patient is sufficiently recovered to be discharged, is to give him a broom and put him in a room with a water-tap turned full on. If he proceeds placidly to sweep up the water without turning off the tap, his standard of intelligence is not deemed to be high enough. The individual who endeavours to get rid of the fly danger by killing individual flies, and at the same time allows their breeding places to remain unheeded is intellectually not far removed."

Mr. J. H. E. Winston, Wills librarian, Guy's Hospital, continues the interesting and useful series of "Bibliographies of Guy's Men," with Nos. 4, 5, and 6, containing the bibliographies of the published writings respectively of Sir H. G. Howse (1869–1904), Dr. P. H. Pye-Smith (1866–1910), and Mr. Thomas Bryant (1856–1902). The preceding bibliographies, some of which have been noticed in our columns, are those of Sir Samuel Wilks, Mr. James Henry Targett, and Sir W. Arbuthnot Lane.

J. M. A.—According to "The Modern Materia Medica," published by the *Druggists' Circular*, New York, "Echafolta" is an eclectic preparation of the plant *Echinacea angustifolia*, intended as an internal antiseptic and alterative. Dr. J. Coplin Stinson has written as follows, in the *New York Medical Journal*, concerning the plant: "Echinacea ...... is a mildly stimulating non-toxic, antiseptic, an antizymotic, alterative, anodyne, restorative, and aphrodisiac. It has been used internally in malarial disease, typhoid and other fevers, syphilis, diseases of the stomach, diphtheria, septic poisoning, anæmia, erysipelas, cancer, snake and other bites, and impotence; locally, in diseases of the teeth, gums, and throat, wounds, ulcers, sloughing, snake and other bites, hæmorrhoids, cancer, boils, carbuncles, urethritis, elytritis, different forms of erythema, erysipelas, and impotence." The remainder of the article is devoted to extolling its aphrodisiac virtues as a local application.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common, S.W.

WEDNESDAY—9 P.M, Bolingbroke Lecture:—Sir W. Arbuthnot Lane.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Clinics:—10.30 A.M., Surgical Out-patients (Mr. E. Gillespie). 2.30 P.M., Medical Out-patients (Dr. T. R. Whipham); Gynæcological Out-patients (Dr. Banister). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

TUESDAY.—2.30 P.M., Surgical Operations (Mr. Carson). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. Howell Evans); Nose, Throat, and Ear Out-patients (Mr. H. D. Gillies). Radiography (Dr. Metcalfe). 3.30 P.M., Medical In-patients (Dr. A. J. Whiting). 4.30 P.M., Special Lecture:—Mr. T. H. C. Benians: Pathological Data in Cerebro-spinal Fever and their Bearing on Diagnosis, Prognosis, and Treatment.

WEDNESDAY.—Clinics:—2.30 P.M., Throat Operations (Mr. Gillies). Children Out-patients (Dr. T. R. Whipham); Eye Out-patients (Mr. R. P. Brooks); Skin Out-patients. 5.30 P.M., Eye Operations (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations (Dr. A. E. Giles). Clinics:—Medical Out-patients (Dr. A. J. Whiting); Surgical Out-patients (Mr. Carson); Radiography (Dr. Metcalfe). 3 P.M., Medical In-patients (Dr. R. M. Leslie).

FRIDAY.—2.30 P.M., Surgical Operations (Mr. Howell Evans). Clinics:—Medical Out-patients (Dr. A. G. Auld); Surgical Out-patients (Mr. E. Gillespie); Eye Out-patients (Mr. R. P. Brooks).

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M. Clinical Lecture.

ROYAL SANITARY INSTITUTE, Civil Court, Guildhall, Bristol.

FRIDAY.—11 A.M., Provincial Sessional Meeting. Discussion on the Co-ordination of Military and Civil Sanitary Services in War time (opened by Lieut.-Col. D. S. Davies, R.A.M.C.(T.F.), and Mr. L. S. Mackenzie. The following are expected to take part in the discussion:—Mr. W. Harpur, Dr. W. G. Savage, Dr. W. H. Symons, Mr. J. Tubb-Thomas, and Mr. C. Wintle. 2.30 P.M., By motor-charabanc to Saltford to inspect the Bath New Sewage Works, and to Twerton to inspect the Pumping Station (conducted by Mr. W. H. Radford).

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD, AND CO., 51, Fifth Avenue, New York, U.S.A.

Hunterian Lecture

ON

SOME CONGENITAL LESIONS OF THE SMALL INTESTINE.

THEIR ORIGIN AND CLINICAL BEARINGS.

Delivered before the Royal College of Surgeons of England on March 10th, 1915,

By J. HOWELL EVANS, M.A., M.B.,
M.Ch. Oxon., F.R.C.S. Eng.,
HUNTERIAN PROFESSOR; SURGEON TO THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM, N., ETC.

Mr. President and Gentlemen,—Malformation is the term applied to any disturbance of the anatomical structure of the body which originates during intra-uterine life. From very early times such deviations from the normal have been studied. Teratology is no new science. Accurate observations by Caspar and Friederich Woolf, later endorsed and promulgated by Meckel, revolutionised the accepted significance of anomalies and malformations; many deviations in higher types may be regarded as the normal condition of lower forms. Nevertheless, antenatal pathology is to the majority of medical men an unknown land; to the student of embryology no more fascinating subject could be presented than the field of congenital lesions of the small intestine. To me antenatal pathology has been a subject of ever-deepening interest, because it is a subject of tremendous importance for the future of the race and the individual.

Antenatal pathology, being concerned with all the morbid processes which act upon the organism before birth and with the effects which they produce, may be considered from three points: 1. Fœtal pathology. 2. Embryonic pathology, teratology. There is good reason to believe that morbid agencies acting on the embryo produce not diseases but malformations. When the malformed embryo becomes a fœtus it carries its malformation with it. 3. Germinal pathology. The lines along which the future growth is to take place are nearly all fixed during the embryonic period—i.e., the first six weeks of intra-uterine life. Since the chief physiology of the embryo is organogenesis, or formation of parts and organs, so the chief effect of pathological processes in this embryonic or formative period is the malformation of its parts and organs.

Constrictions, Occlusions, and Kinks.

Several hypotheses have been put forward in explanation of atresiæ and stenoses of the small intestine—viz., (1) Intra-uterine peritonitis; (2) ulceration, ulcerative contraction; (3) pressure from tumours; (4) pressure from amniotic bands; (5) embolism or thrombosis of the superior mesenteric vessels; (6) inguinal hernia, volvulus, intussusception; (7) traction of the omphalomesenteric duct; (8) enlarged valvulæ conniventes; and (9) non-liquefaction and non-disappearance of the epithelium-occlusion and ingrowth of the mesenchyme.

One reason why the majority of these hypotheses give the impression that they are mere suppositions is probably to be found in the clinical factor which has played so great a part in the discussion of the etiology of congenital intestinal atresia, and which is found to-day overpowering the surgery of intestinal bands and kinks. It is inconceivable how peritonitis can give rise to formations of the anatomical structure as shown in these occlusions, &c. It is the distinguishing characteristic of all these malformations that the parts of the intestinal wall in relation with the peritoneum are unchanged, and that only the innermost layer is the seat of a pathological process.

During the nineteenth century another hypothesis, in which fœtal volvulus is considered to be the common etiological cause, appeared extensively in the literature of the subject. As in clinical matters innumerable the effect has been taken for the cause, so that any associated volvulus should be looked upon as secondary to the atresia and not the cause of it. Such a causation as fœtal intussusception, suggested by Chiari and advocated by Braun, presupposes intra-uterine mechanical occurrences different from those known to occur in extra-uterine life. Vascular irregularities of the intestine or vascular lesions arising from infections or intoxications, transmitted *via* the placenta, which have been favourably viewed as causes, are hardly likely to produce localised epithelial defects.

Credit is due to Bland-Sutton for drawing attention to the occurrence of malformations at the seat of "embryological events." This view offers a feasible explanation of "perivaterian diverticula" and of ileal constrictions or even occlusions within the zone of Meckel's diverticulum due to super-involution of the omphalomesenteric duct, but not of those malformations close to the ileo-cæcal valve nor of multiple stenoses, nor yet of stenoses situated high up in the intestine.

The first to study the etiology of congenital atresia of the small intestine was Meckel; his views approach more closely to those now accepted than all the hypotheses of the past hundred years. Meckel introduced a normal theory of evolution as the basis of teratology, showing that several malformations are due to the arrested development of early embryonic stages; and he pronounced in principle the important law promulgated in later years by Haeckel as the "principle of biogenesis."

It is a curious fact that nearly one hundred years had elapsed before fresh researchers sought to take up the path so enthusiastically finger-posted by Meckel in order to solve the question of the etiology of congenital atresia of the intestine, and this is all the more astonishing when we consider how unscientific and inferior to Meckel's standard the hypotheses have been which have since prevailed. Few pathologists have worked at the etiology of atresiæ and kinks as falling within the evolutionary theory, and no one had filled up a gap in our knowledge of the development of the intestine until the further investigation and application by Forssner of the discovery made by Tandler.

The earliest stages only became the subject of exact investigation when Tandler commenced his work on the earliest development of the duodenum in 1900. Tandler's hypothesis, which has a totally different basis from any of the aforementioned views, may now be considered.

The Epithelium-Occlusion Theory.

Having found that a temporary epithelium-occlusion completely obliterating the lumen is a normal occurrence in the duodenum Tandler concluded that sometimes this embryonic atresia may persist and be found as a congenital occlusion or stenosis. In 1907 Forssner found that in early embryos the lumen of the duodenum was completely obliterated in places. This normal epithelium-occlusion of the duodenum disappears by a process

No. 4789.

of disintegration, leading to a condition which presents the appearance of vacuolation as seen in Gruyère cheese. Forssner's opinion is that this epithelium-occlusion may take place throughout the small intestine. Further, when followed by an ingrowth of mesenchyme this will account for duplications, for single or multiple occlusions in those segments of the small intestine which enter neither into the duodenum nor the segment of Meckel. The lumen of the duodenum is finally formed by the fusion of the vacuoles, which were discovered and described independently by Kiebel and by Lewis and Thyng. Further, Tandler considered the cause of the occlusion was due to the resistance exerted upon the expanding epithelium by the surrounding mesenchyme.

The actual frequency of any internal congenital lesion cannot be computed at present because of the want of that "systematic examination of the still-born" which has been advocated by Bland-Sutton.

The embryonic epithelium-occlusion develops into a complete atresia by the mesenchyme growing into this epithelium before its disintegration has commenced, thereby making the simple epithelial septum a more permanent structure. The iris-like membrane may well originate in a similar manner because the connective tissue is incomplete or so weak that at one spot it yields to the pressure of accumulated material in the proximal segment; crescentic membranes may have a similar origin. By subsequent changes a thick obstruction may be attenuated so as to form a membrane or a stenosis may be converted into a valve.

[*By a series of diagrams it was shown how the various primary types of atresia may be brought about after the mesenchyme ingrowth has taken place.*]

EMBRYONIC FACTORS IN REGARD TO THE SMALL INTESTINE.

As we are considering lesions of embryonic origin it would be well, if time permitted, to detail the chronology of embryonic factors in connexion with the small intestine. Certain points, however, cannot be omitted.

The blastodermic vesicle, having been formed, is divided into two secondary cavities: (1) Intra-embryonic, the future intestinal canal; and (2) extra-embryonic, the umbilical vesicle. At first these cavities communicate by a wide gap which is converted into a short canal of small calibre—the vitelline duct. With the growth of the allantois the umbilical vesicle, owing to its diminished function, atrophies and becomes a mere vestige, whereas its attachment, broad at first, becomes reduced to a slender stalk. Such are the conditions present at the end of the first month. A little later the future umbilical cord consists of: (1) The amnion, which forms a covering containing (2) the vitelline group—(*a*) umbilical vesicle, (*b*) vitelline duct, and (*c*) omphalomesenteric vessels; and (3) the allantoic group—(*a*) allantoic pedicle, and (*b*) umbilical vessels. It is between the third and sixth week of intra-uterine life that the vitelline vesicle attains its greatest size. From the fourth month there ordinarily remains no trace of the primary communication between the intestinal canal and the vitelline sac.

A portion of the intestine normally projects like a hernia into the umbilical cord. As the liver grows and crowds upon the rapidly elongating intestine the intestine must escape, and the cœlomic space within the cord receives this "hernia funiculi umbilicalis physiologica." In this umbilical hernia, according to Mall, there are six primary coils which are as definite in the adult intestine as the convolutions are in the brain. It will probably be found that many of the kinks of the adult intestine are originally associated with these primary coils.

MECKEL'S DIVERTICULUM.

The diverticulum ilei, better known as the diverticulum of Meckel, is always single, having its situation upon the ileum, within a metre or so of the ileo-cæcal valve. In structure it corresponds to the ileum. Its calibre is generally equal to, occasionally smaller, but rarely larger than the calibre of the intestine above its point of origin. Though the diverticulum is usually found along the free border of the ileum, lateral and intramesenteric variations occur. The blood-supply is conducted along a special mesentery or mesodiverticulum ending in a small mass of fat or rarely in accessory pancreatic tissue. The implantation upon the ileum may be at a right angle or at an acute angle. Its shape may be cylindrical, conical, or rarely branched, whereas in length it varies from a nipple-like projection of less than an inch to eight inches or even more.

VESTIGIAL REMAINS OF THE VITELLINE DUCT OR OF ITS VASCULAR BUNDLE.

To J. F. Meckel of immortal fame belongs the credit of having recognised that the "diverticulum ilei" and its rarer congenital umbilical fistula are the remains of the embryonic omphalomesenteric duct, and that the bands which pass from the diverticulum or diverticular zone to the umbilicus are the persistent—patent or occluded—omphalomesenteric vessels. Dareste believed that if a sufficiently careful examination were made some slight trace of these vessels would always be found in the form of small filaments.

In animals, like the cat, which are born with a membrane over their eyes, these filaments are commonly found and are associated with the normal narrowing which occurs near the cæcum. Traces of these vessels are most frequently found in the pig, in which animal there is a corresponding greater frequency in the occurrence of the diverticulum of Meckel. Sometimes a considerable part of the persistent omphalomesenteric artery is found coursing beyond the gut and its diverticulum to the umbilicus. In 1883, it is of interest to note, Allen pointed out that remnants of both the omphalomesenteric artery and vein are normally found in the new-born of the cat, dog, and guinea-pig, in a strand of tissue which generally reaches the navel; these filaments or bands are always covered by peritoneum. Much has been written about the various bands and their inflammatory origin, but no inflammatory band is accompanied by vessels of congenital origin, neither is such a band found to be associated with a definite mesodiverticulum. (See Fig. 1.)

Apart from the interest arising out of the evolutionary point there is the immense practical importance attached to these bands because they are found in children otherwise normal and well-fitted to live and propagate, yet these malformations or anomalies may threaten or even destroy life by secondary occurrences.

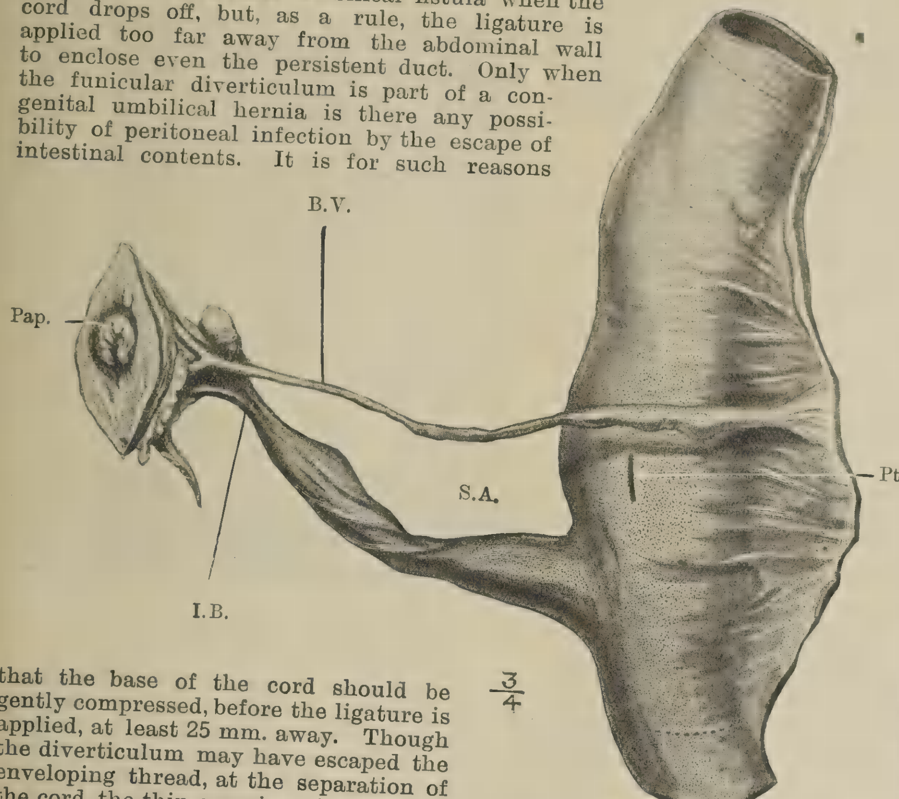
FISTULÆ OF PERSISTENT OMPHALOMESENTERIC DUCT.

Varieties of fistulæ of the persistent omphalomesenteric duct may be distinguished—namely, Series 1, simple cases; Series 2, cases with inversion and prolapse of the mucous membrane;

Series 3, cases of hernia accompanying inversion and prolapse of the mucous membrane; and Series 4, cases of fistula which have caused symptoms of strangulation.

If the omphalomesenteric canal is not obliterated, but continues to develop in its independent manner, it gradually takes on the more complete structure of the small intestine with which it genetically agrees; when the development of this duct attains its maximum it even penetrates into the umbilical cord. It can therefore occur that the ligature of the accoucheur enveloping the persistent duct within the cord may divide the duct with a resulting entero-diverticular umbilical fistula when the cord drops off, but, as a rule, the ligature is applied too far away from the abdominal wall to enclose even the persistent duct. Only when the funicular diverticulum is part of a congenital umbilical hernia is there any possibility of peritoneal infection by the escape of intestinal contents. It is for such reasons that the base of the cord should be gently compressed, before the ligature is applied, at least 25 mm. away. Though the diverticulum may have escaped the enveloping thread, at the separation of the cord the thin covering of the diverticulum will yield under the influence of the least straining or crying of the child.

FIG. 1.



Meckel's diverticulum fixed at umbilicus. The dotted lines indicate the strangulated gangrenous portion. Pap., Papilloma at the navel; the urachus is seen below. B.V., Band; vestigial remains of omphalomesenteric vessels. I.B., Impervious band of attachment. S.A., Strangulating arch. Pt., Point of puncture.

Occasionally small round papillomata, like raspberries, are seen in the umbilical pit; by an imprudent use of the knife, scissors, or caustic the small opening, probably invisible to the naked eye, becomes widened and the undoubted fistulous track is established.

Inversion and prolapse of the diverticular mucous membrane can occur spontaneously directly after the separation of the cord or at a later period, in which case the determining cause is not infrequently a violent attack of coughing, when there unexpectedly appears a tumour of varying size and shape with a fine opening, from which ooze a little mucus and intestinal matters. The umbilical projection behaves like the intussuscepted portion of an intestinal intussusception. When the diverticulum is short and wide, under the influence of increased pressure produced within the abdominal cavity, the juxta-diverticular loop of intestine is projected as through the opening of an artificial anus. It even occurs as a double evagination, the point of separation of the superior and inferior ends presenting itself as a spur between the two loops. The projected intestine becomes œdematous, whereas the contiguous serous surfaces become adherent, so that reduction to remove the impending complete intestinal obstruction is difficult.

DIVERTICULA.

The term "intestinal diverticulum" may be applied to any lateral evagination of the digestive tract. Since the researches of Meckel the name "true diverticulum" is applied to such as result from an embryonic evolutionary disorder; we shall need to differentiate this from another pathological production, the "false diverticulum."

True diverticula are characterised by their constant situation in (*a*) the duodenum and (*b*) the lower portion of the ileum. They consist anatomically of the three regular coats of the intestine with vessels which run in a mesentery. The duodenum is the seat of many developmental irregularities, such as transverse septa and longitudinal folds; it is likewise the situation where several important "embryological events" are crowded together. The embryology of the liver and pancreas demands close study—e.g., the manner in which the primary hepatic diverticulum or median cul-de-sac of the entodermal tube extends as a winged crescentic mass, throwing out extensions and early exhibiting a rounded subdivision (the future gall-bladder and cystic duct), whereas in the angle between it and the duodenum the ventral pancreas has already appeared. Simultaneously or possibly earlier the dorsal pancreas arises at a superior level. Even a paired ventral pancreas has been found in many vertebrates and reported in the human embryo; the presence of a pancreas in the duodenal wall—a cyst and consequent pouch —may be due to this double occurrence. In the duodenal loop congenital diverticula, invariably single, are occasionally found, and the presence of pancreatic tissue in their walls points forcibly to their origin as connected with the dorsal or ventral pancreatic rudiments. It seems well proven that diverticula of the second and third parts of the duodenum are congenital in origin, whereas in the first part three varieties of diverticula occur: (1) congenital; (2) acquired wide-mouth diverticulum of the duodenal vestibule; and (3) ulcer diverticulum.

In the jejunum no "embryological events" complicate the simple tubular structure. Accordingly the majority of jejunal diverticula are false or acquired diverticula. Nevertheless, as the epithelial lining precedes the development of the mesenchyme, so an embryonic irregularity of the epithelium may lead to a protrusion which never becomes covered by muscle tissue and consequently, by a progressive increase in size concomitant with the growth of the individual, this finally attains to a considerable size, when it is wrongly labelled "acquired." Observations applicable to the jejunum are likewise applicable to the ileum, in connexion with which the wider subject of Meckel's diverticulum will be considered.

CONDITIONS DUE TO PERSISTENT OMPHALOMESENTERIC DUCT.

Of all the conditions which arise from the persistence of the omphalomesenteric duct or vascular bundle the most frequent is undoubtedly intestinal obstruction. This complication, which is one of the gravest, has long been known. Internal strangulation associated with a diverticular fistula has for its causation bands or loops to which I shall presently make further reference.

Intussusception of Meckel's diverticulum, when the diverticulum is fixed and patent at the umbilicus, is very rare. Nevertheless, even an instance of a retrograde diverticular intussusception—i.e., in which the distal end of the intestine became invaginated—has been placed on record. Also the diverticulum when free becomes inverted and, acting as a polypus, causes an intussusception, or the invagination of the intestine is produced in the proximity of a diverticulum without its walls being turned in.

Volvulus of the diverticulum of Meckel belongs to the category of curious pathological and rare occurrences. There are only four cases in literature, to which may be added the case now illustrated by means of the epidiascope.

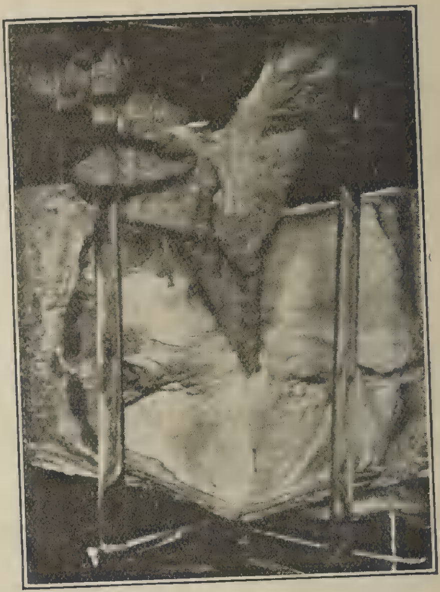
Hernia of the diverticulum of Meckel may be found at birth: firstly, as the only content of the hernial sac—in this exceptional occurrence its interest, as previously stated, is in connexion with the entero-umbilical fistula which may arise therefrom; or, secondly, associated with other portions of the intestine, when we have a matter of omphalocele—only observed after death or where life is impossible, and accordingly of no practical importance. The occurrence, later in life, of a hernia containing a diverticulum of Meckel is more frequent and of greater practical interest. The diverticulum when free is essentially mobile, and, being connected with the lower part of the ileum, is liable to become herniated. In 1700 and 1701 Littré and Méry communicated to the Academy of Sciences cases of diverticular hernia, which have since been denominated "hernia of Littré," and are most frequently met with in the hernial regions of the right side, though found from time to time in inguinal, scrotal, or femoral herniæ of the left side.

DIVERTICULAR STRANGULATION.

The diverticulum, being an integral part of the small intestine, is subject to the same affections, such as enteritis, ulceration, perforation, abscess, and peritonitis; but the particular condition is obstruction by a diverticular knot, by congenital or inflammatory bands leading to a compression. Diverticular strangulations therefore fall into two large classes: (1) When the diverticulum is fixed; and (2) when the diverticulum is free.

The diverticulum may be fixed to the mesentery, to the small intestine, to the cæcum and vermiform appendix, possibly to other viscera or the abdominal wall, but the immediate consideration deals with the diverticulum congenitally attached to the umbilicus directly or indirectly by bands which contain the vestigial remains of the omphalomesenteric vascular bundle. The production of strangulation may depend upon progressive constriction, upon a diverticular ring engaging one or more intestinal loops and acting like a true hernial orifice, upon a diverticular band attached to the umbilicus, or upon free filamentous prolongations. A twist is produced towards the middle of the cord and forms a ring in the most relaxed part, a loop of intestine becomes engaged in the opening, and the collar now stretched will straighten out again and embrace it more tightly. At other times the intestinal loop will entwine itself around the diverticular filament by a twisting movement on its own axis.

FIG. 2.



A view of the peritoneal surface of the anterior abdominal wall showing a diverticulum of Meckel herniated at the umbilicus. (Specimen in Musée Dupuytren, Paris.)

Strangulation by Diverticular Knots.

Two conditions need to be considered in connexion with strangulation by knots when the diverticulum is free in the abdominal cavity: (1) The diverticulum remains free up to the occurrence of strangulation; and (2) the diverticulum contracts secondary adhesions to neighbouring organs. To become a cause of strangulation it is necessary that the diverticulum be of such a length as to allow it to encircle the intestine and find its distal extremity snared between its point of origin and the strangulated loop, while its free end must be sufficiently dilated not to slip readily from the grip which has been made upon it.

Occlusion by diverticular knots constitutes one of the most remarkable phenomena in abdominal pathology. Parise's (1851) description of two varieties of diverticular knots has become classical: (*a*) The knot with a single loop; and (*b*) the knot with a double loop.

As to (*a*), the diverticulum grasps the loop immediately above or below, turns around its pedicle, passes below its own point of origin, placing itself between this and the intestine from which it arises, and lastly becomes dilated into an ampulla. (See Fig. 3.) Treves among others considers the terminal ampulla secondary, but its primary occurrence has been proven, and to Parise this is the indispensable requirement to hinder the slipping of the knot, so that the loop can only be disengaged by puncture of the diverticular ampulla.

In (*b*), the second variety of diverticular knot, two loops are found to be taken into its embrace—the one immediately above, and the other immediately below the origin of the diverticulum. Of these two loops one is indispensable, presenting the characteristics of the loop comprised in the simple diverticular knot, and is analogous to that of the simple knot called by Parise the "nodal loop." The presence of the secondary or accessory loop is understood by appreciating that the diverticulum had executed a complete rotation upon its axis before gripping the nodal loop. This Parise called the "rotatory loop."

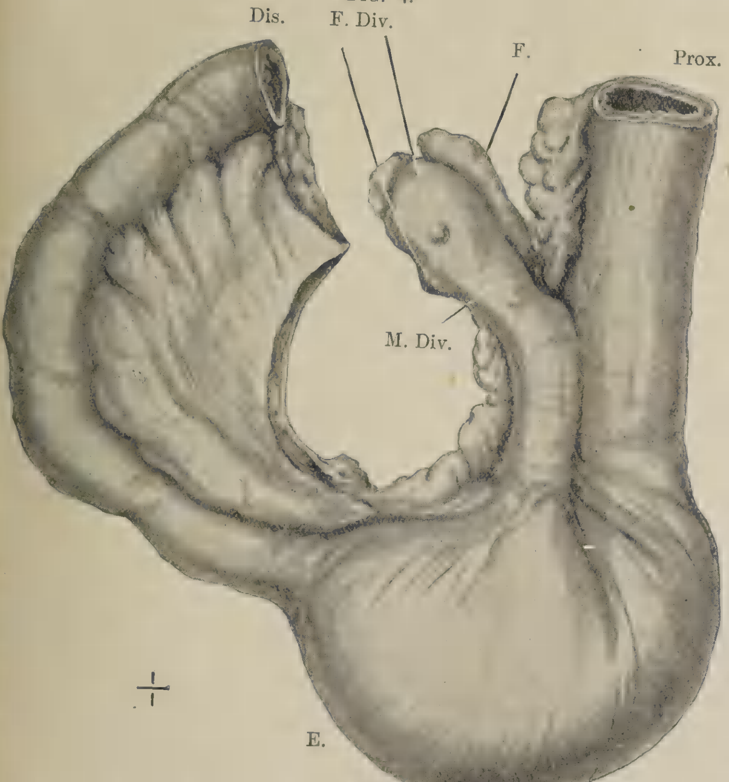
DIVERTICULITIS.

Diverticulitis or inflammation of Meckel's diverticulum—the post-embryonic remains of the omphalo-mesenteric duct—ought no longer to be ignored. The structures which enter into the wall of the diverticulum being identical with those of the small intestine and its evagination comparable to the appendix vermiformis, any analogy, becomes admissible, if established between the pathology peculiar to these two appendices—appendix ilei, appendix cæci.

The frequent occurrence, at the distal end of a true diverticulum, of false diverticula (see Fig. 4) whose walls are incomplete explains the ease with which a perforation may be produced and the rapid extension to the peritoneum of a diverticular infection. Similar anatomical dispositions, an analogous structure and a direct communication with the intestinal tract allow of inflammation in the appendix ilei in the same way as in the appendix cæci. Concretions or foreign bodies may provoke congestion of the mucous membrane and even produce erosion or obstruct the intestinal ostium; these may all in their turn be adjuvants, but the sole determining cause of diverticulitis is *infection*. The clinical features from the transformation of the diverticulum into a closed cavity in which is produced a focus of infection, with subsequent septic intoxication, or from the invasion of the diverticular wall proceeding to not only a peridiverticulitis but even to a widespread peritonitis, are comparable to those of an appendicular infection. The widely open ileal ostium, even if it renders a closed cavity more difficult, allows of the free access of parasites

FIG. 4.



Specimen illustrating extensive stenosis. F. Div., False diverticula. F, Fat. Prox., Proximal end of intestine with hypertrophied wall. Dis., Distal end of intestine with narrow lumen. M. Div., Meckel's diverticulum. E, Enterocyst.

and foreign bodies which play a certain part in the etiology of diverticulitis. The various pathological affections—e.g., tubercle and typhoid—which attack the ileum can extend to the diverticulum. The part played by mechanical circulatory troubles which are so often observed must not be neglected.

Diverticulitis presents no distinguishing clinical characteristic to guide the surgeon. As diverticulitis is little known, and as the phenomena it provokes are produced by other lesions, there is no wonder that the condition is invariably taken for other lesions until operation reveals or necropsy evidences the true condition. "As many cases of diverticulitis as come before us, so many errors of diagnosis made" is a remark which stigmatises our very imperfect ability to unerring diagnosis of intra-abdominal lesions.

[*A series of diagrams, drawings, and specimens were shown illustrating the chief points in connexion with the production of diverticulitis, peridiverticular abscess, diverticular pyo-stercoral fistulæ, &c.*]

Cysts of Vitelline Origin.

Cysts which are of vitelline origin may be classified according to their situation: (1) Intramesenteric or retroperitoneal; (2) diverticular, (*a*) enterocyst of Gfeller, (*b*) enterocyst of Roth, and (*c*) enterocyst of free diverticulum; (3) umbilical, (*a*) retroparietal or properitoneal, (*b*) intraparietal or intramuscular, and (*c*) proparietal or subcutaneous; (4) funicular; and (5) terminal.

Beyond the hernial sac in the new-born, and yet within the dependent portion of the umbilical cord, small cysts have been found containing viscid fluid and proved to be distended unobliterated vitelline portions, to these I have applied the name of "funicular cysts." If a systematic examination of the cord and placenta of all still-born was instituted I doubt not but that many a funicular cyst as well as many a terminal cyst—i.e., of the remains of the yolk sac—would be revealed.

Umbilical cysts of vitelline origin comprise those varieties which are in close relation with the anterior abdominal wall. These cysts are very rare; not more than ten instances which have been authentically proven as having a definite vitelline origin have been recorded. These cysts represent the persistence of the distal portion of the omphalomesenteric duct with any filament or band which may connect its posterior wall to the small intestine or mesentery. The open cysts, in all probability, result from the necrosis of the extreme end of the diverticular remains.

In connexion with enterocystomata it is very interesting to observe that in birds after the yolk-sac has been drawn into the body-cavity its stalk remains in connexion with the intestine, forming an appendix like a small cæcum. This often persists throughout life in the Nidifugæ, and occasionally as in the Ratitæ retains some degenerated yolk but does not remain in communication with the ileum. In the Nidicolæ or Altrices it is generally absorbed before maturity. Though in the newly hatched chick the yolk-sac should atrophy completely it may form a cyst of considerable size, as is well illustrated by a specimen from an emu—in the Museum of this College—in which the pedicle is twisted. Some free diverticula show evidence of a progressive constriction which may ultimately lead to a retention cyst, but this variety is more liable to become the seat of a diverticulitis, as is also the case when the intestinal orifice is almost closed by a circular valve of reduplicated mucous membrane.

Intramesenteric cysts—cysts the origin of which is correctly ascribed to the vitelline duct—may be found attached to the intestine, to the distal border of the mesentery, or lying within the mesentery. The cyst wall includes all the usual layers of the intestinal wall. Little had been mentioned about the vitelline origin of these cysts until Dowel in 1900 reviewed the subject. Terrier and Lecène have collected 18 instances of juxta-intestinal cysts, which they regard as derived from the remains of the omphalomesenteric duct. Some intramesenteric cysts may be the outcome of other diverticula of the small intestine. Again, cysts in the mesentery may have originated behind the peritoneum and migrating forward between the layers of the mesentery come into contact with the intestine.

ON THE BACTERIAL FLORA OF WOUNDS PRODUCED DURING THE PRESENT WAR.[1]

By LEONARD S. DUDGEON, F.R.C.P. Lond.;
A. D. GARDNER, M.A., D.M. Oxon., F.R.C.S. Eng.;
and
F. BAWTREE, M.R.C.S., L.R.C.P. Lond.
(*From the Department of Pathology, St. Thomas's Hospital.*)

It is merely our intention in this communication to refer to the bacterial flora of wounds of various kinds produced during the present war. We have selected some hundred cases from our series of observations on superficial and deep injuries of the bones and soft parts produced by shell, shrapnel, and bullets. It is improbable that a selection of a larger number of cases would prove of greater value, as the bacterial flora falls into two important groups which are fully represented here. We merely recite these results with the hope that they may serve to emphasise the importance of certain bacteria in the varieties of infected wounds which surgeons and others in charge of such cases have to deal with. We have avoided any reference to treatment, as this is a question which is very much under discussion and largely depends on the bacteria which are present in the infected tissues.

We may mention at the outset that as the work was done in this country we have no records which actually refer to the type of bacteria found *directly* after injury. It would seem most probable, however, that the bacteriology of a recent wound is merely the bacteriology of manure implanted in damaged tissues. The fact which appears to be of greatest interest is the close similarity of the bacterial flora of these wounds to the infection of the tissues such as occurs among civilians in any large hospital. There is the closest similarity between the bacteriology of severe injuries of the soft parts produced by shrapnel and injuries in civil life infected with horse-dung.

In severe traumatism met with in this way there is usually infection of the damaged tissues with the B. aerogenes capsulatus, streptococci, and coliform bacilli. If the patient dies from a rapid infection it is generally caused by the gas gangrene bacillus; if he survives streptococci often take chief command of the infection. This is the bacteriological history of many of these shrapnel wounds. It has appeared to us from previous experience of gas gangrene that the mere presence of the B. aerogenes capsulatus is not the important factor in a wound, but it is the presence of this organism in tissues which are under considerable increase of tension that is of such extreme importance, and experience gained during this investigation tends to confirm this view. Our cases have been selected so as to afford examples of the varieties of injuries, and to compare the bacteriological findings of the comparatively slight superficial lesions with the deep and severe wounds of bone and soft parts. The most important group of bacteria from many aspects is the anaerobic family, among which the bacillus of tetanus and the B. aerogenes capsulatus are the most important members.

---

[1] The clinical material was derived from St. Thomas's Hospital, the 2nd London General Hospital, and from private sources. A grant has been made from the National Research Committee towards the expenses of the investigation on wound infection.

It is the relation of these anaerobic bacteria to the diseases to which they give rise that is of greatest importance to the surgeon. It is for that reason that we have considered separately the survival of the anaerobic group of bacteria in the tissues to which we shall refer in some detail. No account will be given of the technique employed, but in every instance a complete detailed examination was made. It will suffice to emphasise the value of the liquid egg and veal medium of Besredka, for it is impossible to over-estimate the advantages this medium offers both for the cultivation of the aerobes and anaerobes; in fact, without it we should have failed on many occasions to detect the anaerobic bacteria in the infected tissues.

Pathogenic Anaerobes.

No.	Length of history.	Other bacteria present.	Anaerobe.
1	3 days.	B. coli.	B. tetani.
2	14 "	Staph. albus.	"
3	9 "	B. coli; Diphtheroid bacillus.	"
4	13 "	Staphylococcus; Unclassified bacillus.	"
5	11 "	Streptococcus; B. coli; Staphylococcus; Diphtheroid bacillus.	"
6	49 "	B. coli.	"
7	7 "	"	"
8	65 "	B. proteus.	"
9	6 "	Streptococcus; Staph. aureus.	B. tetani and B. aerogenes capsulatus.
10	28 "	Streptococcus; Staphylococcus; Unclassified bacillus.	"
11	11 "	Staph. aureus; Diphtheroid bacillus.	"
12	2 "	None.	B. aerogenes capsulatus.
13	5 "	Staph. aureus; B. proteus.	"
14	8 "	Staph. albus; Unclassified bacillus.	"
15	9 "	Staph. albus.	"
16	11 "	Staphylococcus.	"
17	22 "	Staph. aureus.	"
18	6 "	Staph. albus.	"
19	5 "	B. coli.	"
20	26 "	Streptococcus; Staphylococcus; Diphtheroid bacillus.	"
21	14 "	Staph. aureus; Unclassified bacillus.	"

Wounds in which pathogenic anaerobes were found.—Twenty-one wounds in all yielded cultures either of B. tetani or of B. aerogenes capsulatus, or of both. The majority of these wounds entailed considerable damage to the tissues, but they were of all varieties, ranging from a trivial skin-wound to a severe and extensive compound fracture of a long bone—in fact, there was no special feature of clinical interest to suggest the importance of the bacteriological findings.

The table shows that with a single exception every wound was infected with aerobic bacteria in association with the anaerobes. The exceptional case was that of a superficial shrapnel wound in the neighbourhood of the knee-joint; the joint cavity was infected, although the synovial membrane was intact. From the pus which was evacuated from the interior of the joint a pure culture of B. aerogenes capsulatus was obtained, and here it was evidently behaving as a simple pyogenic bacterium. The after-history of this case gave nothing to suggest to those in charge that they had been dealing with suppuration produced by the common organism of gas gangrene. Guinea-pigs inoculated with a culture of this organism died within 24 hours from a rapidly spreading gangrene of the tissues.

In every other case we have found either a staphylococcus, B. coli, or B. proteus in the wound. The frequency with which B. coli appears with B. tetani suggests that its presence may be particularly favourable for the survival of this anaerobe. Of the 11 patients in whose wounds the bacillus of tetanus was found nine had been treated prophylactically with tetanus antitoxin at an early date, and at no time did any one of these exhibit any symptoms of tetanus. Two had not received any prophylactic injection, and of these one developed the disease[2] and the other did not. The last-mentioned case serves to demonstrate that a wound may become infected with B. tetani without tetanus resulting, and that quite apart from the question of antitoxin. There is, however, no reason to doubt that the prophylactic injection of antitoxin has been the means of saving the majority of these patients from the most serious disease arising from wound infection.

It is therefore of considerable importance to realise that a wounded man may be acting as a carrier of these dangerous bacilli for at least *two months* after the date of the wound, and probably for a much longer period, without any reason on clinical grounds to suggest that these bacteria are present in the tissues.

Whatever the nature of the wound, whether it be slight or severe, without a careful bacteriological investigation it is impossible to be sure there are no tetanus spores lurking in its depths. B. aerogenes capsulatus was found on 13 occasions. Although its presence was not confined to any single type of lesion, yet we gradually learned to suspect certain varieties of wounds of harbouring it. Deep wounds with considerable damage to soft parts or bone, with a profuse and perhaps offensive discharge, are the most liable to yield cultures of this organism. It seems certain that some special conditions must be present in order that B. aerogenes capsulatus may give rise to gas gangrene, and that in the majority of infected wounds it is either rapidly eliminated or it settles down to a purely pyogenic or even saprophytic life. One would naturally expect to find an organism of this nature more frequently in recent than in old wounds, and on the whole we have found this to be so. Nevertheless, the table shows that the bacillus is able to survive at least four weeks from the date of the infection.

The facts here presented concerning these two potentially virulent and highly resistant spore-bearing organisms make it undoubtedly very advisable that special precautions should be taken in the sterilising of surgical instruments which have been used in operating upon wounds. Occasions occur when instruments are merely "introduced" to the boiling water, but our bacteriological findings are sufficient evidence of the danger that may arise, more especially with the massing together of wounded which must take place owing to the present circumstances. In one instance a culture of the B. aerogenes capsulatus was obtained from a suppurating wound, but the bacteriological findings were not taken into account. The limb was amputated, but death occurred from rapidly spreading gas gangrene within 30 hours.

---

[2] Wounded at Ypres on Nov. 16th, and received antitoxin at onset of tetanus on Nov. 28th with good result.

The bacillus coli and unclassified coliform bacilli.—In 11 cases a true colon bacillus was isolated from the tissues and gave the recognised tests for this group of bacteria, while in 15 instances coliform bacilli were cultivated. Full cultural tests were applied in every instance, but the results were too varied to assist us in classifying these bacteria. In many instances these coliform bacilli were tested on guinea-pigs or mice by subcutaneous and intraperitoneal inoculation, but no fatal result ensued. Now as to the importance of these bacteria in the tissues. Although the B. coli is capable of exciting a rapidly spreading infection of the peritoneum, yet a similar infection of the connective tissue is uncommon. Experience teaches us that a rapidly spreading infection of the tissues which resents active interference is generally a streptococcal infection in spite of the presence of the bacillus coli or a coliform bacillus in the discharge, but owing to the difficulty in isolating streptococci under such circumstances the presence of these bacteria may not always be recognised. We have no record of an actively spreading infection of the tissues or severe irritable wound from which colon bacilli or coliform bacilli have been obtained in pure culture, but always in association with streptococci, which corresponds with infective lesions of a similar type met with in ordinary practice.

It may be of interest to mention that the B. coli and coliform bacilli were cultivated from lesions widely different clinically, such as a surface granulating wound of the hand with little discharge, and a foul suppurating and deep tissue infection with copious exudate. In two instances out of the total of 26 a colon bacilli was present in pure culture, and in each case the discharge was slight in amount and the temperature was normal.

B. proteus and B. pyocyaneus.—True proteus bacilli were isolated from 5 cases and an atypical proteus bacillus from 2. These cases were all examples of chronic tissue infection with sinus formation and abundance of purulent discharge. The B. pyocyaneus was found in 4 cases, all essentially chronic, with copious discharge from deep wounds, exactly the type of lesion this organism produces among civilians.

Streptococci.—Streptococci were cultivated from 41 of this 100 cases, and in all but a few instances the strain was isolated and put to a considerable number of tests. They were found with about equal frequency in recent wounds (1–2 weeks) and in wounds of longer standing (3–10 weeks). Some 30 strains were grown in the customary series of sugar-containing media in order to test their powers of fermentation, and, if possible, to group them according to some commonly used system of nomenclature, such as that of Gordon. But these tests were found to be of no assistance either towards classification or towards estimation of the virulence of the cocci. Numerous strains were also tested for hæmolysis and for pathogenicity to mice. In the hæmolytic test we made use mainly of a fluid medium consisting of citrated broth to which a little fresh sterile human blood had been added. Occasionally a blood-agar slope or plate was primarily employed, but if this test proved negative it was always repeated with the fluid medium, which contained human red cells and plasma, since this method was found to be more reliable.

Of 19 strains thus investigated 16 were hæmolytic and 3 were not. Nine of the hæmolytic strains were injected intraperitoneally into mice, with the result that 7 were pathogenic and 2 harmless. Of the 3 non-hæmolytic strains, 2 were tested upon mice, with one positive and one negative result. The strain which failed to hæmolyse, but was pathogenic to the mouse, was isolated from a brain lesion due to shrapnel. The patient was operated upon and developed diffuse meningitis shortly after the operation; a streptococcus (presumably the same strain) was grown from the cerebro-spinal fluid, and now proved to be both hæmolytic and pathogenic to mice.

Thus, on the whole, the power of hæmolysing human blood tends to run parallel with that of causing acute disease in the mouse. But neither of these phenomena appears to throw much light upon the question of actual virulence to the human being. It is quite common to find strongly hæmolytic streptococci in trivial healing wounds which are giving rise to no appreciable constitutional disturbance. Therefore one may conclude that a hæmolytic streptococcus although highly virulent may be held in check in the tissues from which it was cultivated.

These wound streptococci often appear to possess only a low degree of virulence, yet it is well to remember that they are capable of undergoing a sudden great increase of virulence if the barriers of protection which the body has set up be broken down by an over-zealous operator or even by quite insignificant manipulation.

The diphtheroid group.—Diphtheroid bacilli were met with on 15 occasions, but clinically the sources from which the bacilli were cultivated were various. Some were granulating wounds, others were deep sinuses—in fact, no special type of wound in particular. These bacilli could not be credited as the direct cause of the infection, although indirectly they may play an important part. In some instances they grew more abundantly anaerobically than in an atmosphere of oxygen, and examples were met with of an orange growth on agar similar to the staphylococcus aureus. Morphological characters were variable, but the most striking type presented the well-known zebra markings.

Staphylococci.—The orange and white staphylococci were cultivated from wounds on numerous occasions, but no further reference need be made to these bacteria on the present occasion.

The striking feature of these results is the persistence of the dangerous anaerobes in the tissues for as long as 65 days from the date of the original injury. It is true that in most cases neither tetanus nor gas gangrene developed, but in one instance a rapidly fatal infection from the bacillus aerogenes capsulatus occurred after an operation.

From a bacteriological aspect it is surprising that the anaerobes do not flourish to a greater extent than even our records show, as every requisite for anaerobic life is present. There is in a deep wound dead tissue, sufficient moisture, and utter darkness owing to the abundance of surgical dressings, while in addition aerobic bacteria which are usually present utilise the remainder of the oxygen. The number of wounded in hospitals and institutions of various kinds at the present time is sufficient reason that every possible advantage that bacteriology offers should be taken so as to avoid the spread of infection from patient to patient, or even in the same patient, quite apart from the actual treatment of wounds by various measures.

THE NAVAL MEDICAL COMMITTEE AND WOUNDS IN WAR: A CRITICISM.[1]

BY J. GODFREY SANER, M.C. CANTAB., F.R.C.S. ENG.,
RESIDENT SURGICAL OFFICER, GUY'S HOSPITAL; LATE CHIRURGIEN-EN-CHEF, THE BELGIAN FIELD HOSPITAL.

THE committee consisting of Sir W. Watson Cheyne, Bart., Fleet-Surgeon P. W. Bassett-Smith, C.B., R.N., and Mr. Arthur Edmunds, M.S. Lond., F.R.C.S. Eng., after experiments carried out on dead material, guinea-pigs, and one man, have issued "borsal" and cresol paste to the navy and the army with the expressed hope that the wounds for a certain period will be treated in the manner suggested in their instructions. The committee, realising the grave responsibility they have assumed in advocating the general use of borsal, appeal to the profession to examine carefully the method and results before passing judgment. In response to this appeal, having seen the results of the treatment in just twice the amount of clinical material at the disposal of the committee, I propose to offer some criticisms on the suggested method.

Sir W. Watson Cheyne had not then been to the front as he tells us, and said that he had no opportunity of testing borsal because "there have been no naval wounded for several weeks, and dockyard and ship accidents have been much fewer than they were." He quotes in all four cases, but one only by the combined borsal and cresol method, and I think it is worth while going over these, as it is really from the results obtained that the committee have advised the issue of the "borsal powder and cresol paste," which, I believe, is now carried on every ship and is being issued to the army.

CASE A.—One was a compound wound of the interphalangeal joint of the thumb. It was a machinery accident with much soiling of the wound. A 20 per cent. carbolic acid paste was at once squeezed into the wound from a paint tube, and from time to time some more was applied on the surface. The interesting point of this case was that although the skin had never been cleaned up or the wound cleaned out, and although practically the entire terminal phalanx was dead, yet for ten days there was no local or general disturbance and no fever, no pain, swelling, or suppuration. On the tenth day the surgeon cleaned it out and applied ordinary dressings. Two days later sepsis appeared, with suppuration up the tendon sheath, just what ought to have been present ten days earlier.

The argument is that there was no suppuration until the tenth day, the infection being kept down by the application of 20 per cent. carbolic paste. Clinically, one knows that machinery accidents very often do not go septic. The sepsis appearing in the tendon sheaths on the tenth day rather suggests that the drainage had been obstructed by the paste, and the tissues were therefore finally attacked. The result of the treatment was death of the phalanx and suppurative tenosynovitis.

CASE B.—Another case was an accidental pistol wound of the buttock with fairly large entrance and exit openings. Carbolic acid paste (20 per cent.) was freely introduced and no inflammation occurred along the track of the wound, and ultimately there was only a small granulating sore at one of the openings, which healed in a few days.

The primary union of clean bullet wounds treated on ordinary surgical lines is proverbial.

CASE C.—A third case was a bad scalp wound with denuded bone which was filled up with a 20 per cent. carbolic acid paste. Here, also, there was no disturbance, and after ten days the small sore which remained was dressed with weak boracic ointment.

That there should have been any sore at the end of ten days is surprising, considering how well scalp wounds heal when treated on general surgical lines. A machinery accident, an accidental pistol wound, and a scalp wound treated at once are in no way comparable to the bulk of the wounds met with in the field.

CASE D.—On the skin cresol is rather more irritating than carbolic acid. As to the action of the paste in wounds we have had only one really test case, that of a man who shot himself in the face and head; the bullet entered just in front of the mastoid process, and ran upwards and forwards and came out at the inner side of the forehead near the middle line. In its course it broke up the upper jaw and the malar bone, passed through the eyeball, tearing it to tatters, and smashed up the lower and anterior walls of the frontal sinus. The fracture of the frontal bone extended into the nose, where also the dura mater was torn, but there were no cerebral symptoms at first. The remains of the eyeball were removed and also one small, quite loose fragment of bone from the supra-orbital region. The 20 per cent. cresol paste was then freely introduced into the whole track and cavity of the wound. The patient lived four days and died of his intracranial injuries, but during that time there was no inflammation or sloughing or suppuration from the wounds; they were quite aseptic, and no bacteria could be found in pieces of blood clot examined on the second and third days. On the second day a cultivation was made from the end of the drainage-tube where it projected beyond the wound, and only six colonies of cocci were obtained. Naturally one would have expected some growth from that part, and it is surprising that it was so little. The patient developed symptoms of meningitis and died on the fourth day. On post-mortem examination suppurative meningitis was found, but there was no suppuration anywhere in the external wound where the paste had been introduced; indeed, although it communicated with the tear in the dura mater, the blood clot was lying in it without any decomposition.

This case was seen and treated by members of the committee. It approximates to the cases less heavily soiled with dirt and filth seen at the front, and yet what result is obtained? The external wound is clean, and suppurative meningitis occurs. I do not for a moment suggest that cases treated by other means do not develop suppurative meningitis, but surely such a case, which remains clean on the surface and septic in the deep and less accessible parts, is not one on which to base a line of treatment contrary to all modern experience and teaching. Further, the treatment in the cases reviewed has not been so successful as to warrant the broadcast issue of borsal powder and cresol paste *with instructions.*

Clinically, the idea that the paste will penetrate to any depth along a bullet wound through muscles is unsound. It is much more likely to drive on ahead any organisms which are at the entrance and which, pent up in a cavity deep in the tissues, will produce a severe suppurative process. If the committee could see some of the wounds, torn and ragged inside, plastered with dirt and pieces of cloth, they would, I hope, shrink in horror from the idea of sealing up this glorious cultivation medium with a greasy plug.

---

[1] Published in the Journal of the Royal Naval Medical Service.

Dr. Willenborg, of the Pasteur Institute in Paris, visited me during April at the Belgian field hospital. He has a roving commission from the French Government to investigate gas gangrene. He told me that the outstanding fact he had learnt which was of value in the treatment of shell wounds and the prevention of gas gangrene was the necessity for thorough cleansing and laying open of the wound—in fact, adequate drainage.

The committee's experiments on guinea-pigs were invariably fatal if there had been any delay in the application of the paste, and in the field, under modern conditions, there must be many hours' delay before treatment. To quote again from the paper:—

> Assuming that radiation takes place *in all directions from the centre*, naturally the further away from that centre the more dilute will be the antiseptic substance.

This assumption is made from experiments with inert substances. It does not consider the living tissue or the serum and the various currents and counter currents produced by the breaking down of cells during the process of repair. Again:

> As a matter of fact, the soiling of wounds with earth is not likely to extend to any great depth, and the borsal, powdered over a wound, especially if it is well open and the bleeding has stopped, will probably overtake the severe infection, while the septic organisms carried on further will be dealt with by the cresol.

The soiling of wounds with earth is found to extend to a very great depth indeed. During the winter the uniforms were caked in mud, and large pieces of cloth were driven into the tissues by bullets and portions of high-explosive shell. In the summer it will be found that the fabric is infiltrated with the dust of battle.

> At any rate, the growth of organisms will be inhibited over a large area, till the patient reaches the dressing station, where the wound can be opened up and more thoroughly attended to.

This may be true in wounds of the saucer type. To make such a statement about deep lacerated wounds with a narrow opening shows unfamiliarity with the conditions existing. The natural out-pouring of serum from the lacerated surface will increase the tension deep in the wound, as the cork of borsal effectually prevents drainage. This bottling procedure is carefully insisted upon in the instructions issued.

The inhibition of growth on the surface of the wound does not matter in the least if, in the end, the depths of the wound are still infected. If members of the committee have tried to inject thoroughly a sinus of some standing with bismuth paste they will know how difficult it is, even in expert hands, and this thorough medication of the wound with borsal or cresol paste must perforce be left to the men in the fighting line if it is to be done at once. If it is to be carried out some hours later, when the infection has got a good hold, I cannot follow the surgery which advocates plugging up the main drain.

To quote further:—

> When the patient arrives at the advanced dressing station the treatment depends on circumstances. 1. If a large number of wounded have to be attended to, patients who have been treated in the above manner can wait, unless a good many hours have elapsed since the injury. In that case the orderlies should inject a little more paste into the wounds and powder them and apply a fresh antiseptic dressing while the patient waits his turn.

The presence of pus, cellulitis, or gas gangrene is not considered. The orderly would, in all probability, not recognise the conditions and simply increase the tension deep in the wound. He would report the case as being dressed, and, from the clearing hospital or dressing station, the man would be sent down to the base, incubating organisms in a carefully plugged living test-tube.

> 2. If it is a large or complicated wound—e.g., a compound fracture—it will be well in the first instance to clean and disinfect the skin, preferably with 1–20 carbolic lotion, then wash out the wound with peroxide of hydrogen and 1–20 carbolic lotion, remove pieces of clothing or accessible pieces of shell, snip away any tags of tissue and arrest bleeding. The wound being dried and held open, it can now be powdered with borsal and some cresol paste left in various parts of the wound. If it is widely open it may be well to put a few interrupted sutures in to bring the edges somewhat together and prevent the escape of the antiseptic and finally apply antiseptic dressings.

The first part of the instructions it might be possible to carry out in a clearing hospital. Certainly, in their entirety, they are impossible in the trenches and in the dressing stations behind the firing line. The second part is simply a résumé of the cleansing of any wound, and as it is obviously meant for qualified men its inclusion seems to be unnecessary. The stitching up of the wound at the end of 24–48 hours, which is commonly the time before the above treatment could be employed, is contrary to all experience gained during this and other wars. Whenever this has been done, almost without exception, the results have been disastrous.

> 3. If it is not a large wound, if the clot seems solid and it has been well powdered and plenty of paste introduced into it in the first instance, it is quite possible that sepsis may not occur, and if that seems likely all that need be done would be to squeeze a little fresh paste and dust some more borsal powder over the surface and the skin around and apply a fresh antiseptic dressing. These wounds will probably not require further dressing till they arrive at the Base Hospital.

If the clot seems solid and not septic, surely it is nature's dressing and should not be disturbed; it is the first process in primary union. If it is disturbed and the surface organisms squeezed into it, it becomes infected, as it is not claimed that borsal destroys the organisms but simply inhibits their growth. The use of the words "quite possible" in the first sentence and "probably" in the second, show that the surmise is entirely theoretical. The issue of the paste, therefore, is an experiment on a large scale based on evidence which is unsound from the bacteriological, pathological, and surgical point of view.

Finally, I quote two cases which are now in Guy's Hospital in the Officers' Section.

CASE 1. *Bullet wound through thigh on May 15th.*—The wound was through the muscles; entrance small; exit somewhat larger. Patient had field dressing applied. May 17th: Borsal powder and cresol paste injected (30 hours after injury). 18th: Operated on at Boulogne. Six incisions made in the thigh, which was very septic, and large tubes put in. 21st: Admitted to Guy's Hospital. Cellulitis was still present, and the patient running a hectic temperature. Further incisions were made and khaki cloth removed. 25th: On fomentations, &c., condition is improving.

CASE 2. *Bullet wound through the leg just above the tendo Achillis on May 16th.*—Seven hours later borsal powder and cresol paste were applied. May 18th: Operated on at Boulogne; eight incisions were made in the leg for cellulitis. 21st: Admitted to Guy's, and it was found necessary to make further incisions. 25th: There seemed a tendency for still further spread, and it may be necessary to operate again.

Both cases quoted are a type of bullet wound which generally gives little trouble and seldom requires this amount of surgical interference.

Sir W. Watson Cheyne, in a letter on May 22nd in the *British Medical Journal*, writes that: "The question of the exact method of dealing with wounds in man was left for further study, and our recommendations were merely tentative and open to alteration as experience indicated." However, the committee were so satisfied with the result of treatment in Case D that the Navy and the Army have been served with the powder and paste. He says that the whole aim of the research was to find a means to delay the growth of bacteria. The substance, cresol paste, did do this on non-living tissue, such as blood-clot, and to a less extent on animals. In its application to the wounds in war the committee recommend practically closing up the septic wounds with this substance, and from the success achieved when cresol was used by the committee, I cannot see their justification in transgressing one of the golden rules of surgery with regard to the drainage of wounds.

The committee assumed that the wound would be opened up, the pastes which had been introduced removed, and the wound thoroughly disinfected and drainage provided, &c. The actual cleansing of these wounds after the use of borsal is no easy matter. A great deal of hot water has to be used before the last trace of the black greasy pus can be removed.

Mr. Arthur Edmunds, who has been associated with the committee in their work, has gone to the Dardanelles. He is evidently armed with the paste, and may proceed to treat the wounds on the lines indicated in the paper. His previous experience has been that of the committee. I hope he will be guided by the conditions found in the field rather than on the assumptions of the laboratory.

THE DIVERSITY OF OPINION CONCERNING THE DIAGNOSIS OF TUBERCULOSIS,

WITH SPECIAL REFERENCE TO THE EXAMINATION OF CONTACTS.

BY G. H. DART, M.D., M.R.C.P. EDIN.,
D.P.H. CANTAB.,
TUBERCULOSIS OFFICER AND ACTING MEDICAL OFFICER OF HEALTH, METROPOLITAN BOROUGH OF GREENWICH.

Now that tuberculosis schemes are coming into operation, all matters concerning diagnosis are of exceptional importance from the point of view of preventive as well as of clinical medicine. The personal element will always enter largely into the diagnosis of difficult cases, but a certain standard concerning fundamentals should certainly be adopted in order to render statistics comparable and permit of correct deductions from statements presented in reports.

The report of the medical officer of the Local Government Board points out remarkable variations in the proportion of notifications to deaths in the returns from individual administrative counties. This may be due merely to failure to notify or to the vexed question of diagnosis. Dr. Newsholme is driven to the consideration of death-rates for his statistics, as he considers that notification of new cases cannot be used as a trustworthy index of the relative prevalence of tuberculosis in different areas.

The reports of the medical officer of the Board of Education illustrate the same lack of uniformity in the consideration of this disease on the part of school medical officers. One of the most remarkable instances of what might be termed the lack of a common basis of diagnosis is given in the 1910 report as follows: "In Worcestershire, for instance, owing to the fact that one of the assistant medical officers diagnosed pulmonary tuberculosis in about 15 per cent. of the children examined, the percentage of cases discovered is 4·18. On the other hand, in Hertfordshire, out of a total of 12,772 children examined, one case of tuberculosis only was discovered." It is, in fact, the diagnosis in children that presents the greatest problem owing to the character of the infection and the tendency to appearance and disappearance of physical signs.

The remarkable prevalence of tuberculosis in children is an established fact. Dr. C. Riviere's figures from THE LANCET[1] are of particular interest as they refer to children who died from some acute disease (e.g., diphtheria) which was not tuberculosis.

	Councilman.	Baginsky.	Heller.	Hamburgher.	Ganghofer.
Number of necropsies ...	220	806	714	150	972
Number tuberculous ...	35	144	140	32	252
Percentage tuberculous	16	18	20	21	25·9

Newsholme,[2] in the section referring to inaccurate diagnosis in children, quotes striking figures from Coates and Landouzy on the question of the prevalence of tuberculosis in children, and also in relation to *deaths*, states that "in children the term broncho-pneumonia not infrequently conceals acute tuberculosis, especially when the 'broncho-pneumonia' occurs after imperfect recovery from such diseases as whooping-cough and measles." This is particularly important as referring to deaths; there is apparently always less reluctance to consider a case with a bad prognosis, tuberculous. In fact, it is to be feared that a recovery is often taken as proof in itself that the case in question was not tuberculous.

It is evident that in the examination of contacts two very important factors bearing on diagnosis are, generally speaking, constant—i.e., family history and exposure to infection. The examination of contacts should therefore show less striking differences in the percentages of positive diagnosis than any other systematic series of examinations, allowing, of course, for the smallness of the numbers. Dispensary reports from all over the country show some considerably different results in this respect, but it will be sufficient for purposes of illustration to quote from some metropolitan reports.

	Contacts.	Found tuberculous.	Percentage.
Paddington and Kensington	920	108	11
Wandsworth	541	54	9
Fulham	668	116	17
Woolwich	666	243	36
Lambeth	306	46	15
Bermondsey	281	85	29
Poplar	668	76	11
Hampstead	204	48	23

At Greenwich a total of 622 contacts were examined by three medical officers. Contacts were found tuberculous at the rate of 10 per cent., 5 per cent., and 18 per cent. respectively.

---

[1] THE LANCET, vol. i., 1910, pp. 156, 185.
[2] The Prevention of Tuberculosis.

There appears to be a tendency to think of tuberculosis only as a condition of local injury, as an infection either of the lymphatic glands or the lungs, or the bones, or other definite parts of the body, and to consider it only from the point of view of the local results. Tuberculosis implies the poisoning of the system with a powerful nervous and muscular poison. The systemic changes are not merely those resulting from underfeeding or malnutrition, or what is generally understood by that term, but the signs of actual toxæmic poisoning. The indications of this are many, as, for example, the flabbiness of the skeletal muscles and at the same time their irritability, the thinning of the trapezius and deltoid muscles, giving the scraggy appearance and sharpening of the point of the shoulder, are particularly noticeable; the dyspepsia, anæmia, and diarrhœa, all of which may be present together; the temperature and character of the pulse; the glandular changes, not necessarily the gross glandular changes due to bacterial invasion of the glands themselves, but the pinhead multiple "micro-adenopathy." These are all manifestations of this powerful neuro-muscular poison.

A systemic poison which can produce such changes should certainly affect also the elastic and muscular tissue of the respiratory apparatus, especially the tissue of a lung exposed to a particular concentration of the morbid products through the lymphatic circulation. There is some reason to suppose that even in purely hilus tuberculosis tidal respiration and percussion note and quality and character of the breath sounds are affected at the apex, perhaps in the same way that loss of "brightening" occurs on X ray examination, though mechanical obstruction must not be forgotten.

Sir Robert Philip has compared tuberculosis with syphilis in this respect of systemic poisoning. The first infection takes place (for the purpose of illustration, by way of the tonsil in the "extra-tonsillar" lymphatic gland), is followed by lymphatic spread and glandular infection, followed again by widespread and various signs of systemic poisoning. It is surely misleading to divide the disease in one's mind as on a notification form into pulmonary or glandular; glandular with attention to glands, only from the point of view of possible caseation or condition of enlargement, and pulmonary with attention to pulmonary physical signs alone. There must be a tendency to do so, because when a report on a child is requested, it is, of course, particularly or altogether a report on pulmonary physical signs which is wanted, and although there may be every other evidence of tuberculosis, pulmonary physical signs may be slight or absent in the earliest stages. Unless, therefore, extreme care is taken, the difficulty of demonstration of pulmonary physical signs in children, and in some cases the evanescent character of the signs, will lead to considerable understatement of the prevalence of tuberculosis.

Then, again, what should be the proof that enlarged glands are in one case tuberculous and in another non-tuberculous—local conditions are misleading. A considerable number of children with an obvious cause for enlarged cervical glands, such as carious teeth, &c., suffer from tuberculosis (as proved by subsequent caseation) which may, of course, in some cases be a superadded condition. Therefore, to exclude as non-tuberculous all those children who show an obvious cause for the glandular enlargement will be to exclude a number of tuberculous. On the other hand, to notify all children with glandular enlargement as tuberculous would be ridiculous. There are also exceptions to every rule, and if a tuberculous infection becomes shut off and its products are unable to pass into the circulation, systemic evidences will not present themselves.

This is, of course, the difference between the infected person—which includes most of the population and must include all contacts—and the person who is really suffering from tuberculosis. There is also an obvious difference between the single, or infrequent, slight infection of the average person and the repeated massive infection which usually falls to the lot of the majority of contacts. Disputed points about which clinicians like Strümpell, Cornet, Fox, and Osler differ from such others as Aufrecht, Krönig, Lees, Riviere, and Goldsheider do not affect the broad aspect of the disease, and it is impossible that these questions could have produced the wide variation in diagnosis referred to. By no means do I wish to imply that the strictest attention should not be paid to the very earliest, slightest, and doubtful or debateable pulmonary signs, but, in fact, to point out that a phenomenon which, taken by itself, may seem bald and unconvincing, may assume a very different aspect when considered in conjunction with a history of infection and the signs and symptoms of widespread neuro-muscular poisoning, so obviously present in many cases classed as suspects or non-tuberculous. And also that many cases, including those (such as broncho-pneumonic and bronchitic) which from the multitude of their physical signs may present extreme difficulty of diagnosis, may have considerable light thrown on them when considered from the point of view of not merely a collection of pulmonary physical signs alone, but of what we know of the disease itself and of the power for evil of its morbid products on the entire system.

If the statistics concerning prevalence of infection are reliable, the probability is that a considerable number of children classed as suspects, or merely ill-nourished, are in reality tuberculous, though this is probably not of much account, as the majority of such children obtain as suspects all that is necessary for complete recovery. An important point, however, is that the first person applying for medical advice is not necessarily the most advanced case in a family with several tuberculous members, and failure to recognise the disease in the first case may mean that the infecting case is not discovered.

As notification is the first step to further investigation, the state of affairs with regard to diagnosis and subsequent notification pointed out by the medical officer of the Local Government Board evidently calls for careful consideration.

Greenwich, S.E.

THE HOME TREATMENT OF SCARLET FEVER.—Mr. V. Gray Maitland, medical officer of health of Nuneaton, in his annual report, after mentioning that the severe epidemic of scarlet fever had practically died out, expresses his conviction that cases treated at home did better and suffered fewer complications than those treated in the isolation hospital, particularly during an epidemic, when the wards were more or less constantly full. The home treatment of scarlet fever as practised in Nuneaton, the results of which were extremely satisfactory, meant that the medical man who notified a case and wished for the services of a nurse could have any treatment he ordered carried out by the nurse. Should the medical man leave the case entirely in the nurse's hands and cease to visit the case himself, the responsibility rested solely upon him, and not upon the borough council.

SOME PRINCIPLES OF DIETETICS.

BY J. SIM WALLACE, D.SC., M.D. GLASG., L.D.S.

SOME fifteen years ago the study of the etiology of dental caries led me to conclude that there must be something radically wrong with dietetic habits which were current in civilised communities. Further, it became impressed upon me that the dietetic precepts emanating from the highest quarters were possibly on the whole productive of harm rather than good, for it was by no means apparent that dental caries and other diseases resulting from bad dietetic habits were less common among the children of professors of physiology than among the children of the relatively ignorant poor. In fact, in time it became evident that the teeth of the children of poor peasants and even of those living in slums were rather less ravaged by caries than were the teeth of those who were supposed to be enlightened in the science of dietetics. Naturally I tried to inform myself in the subject. Among other things I bought a book on "Food and the Principles of Dietetics," and therein found quite a mass of information on the chemistry of foods and certain physiological details associated therewith, but I found remarkably little about the principles of dietetics. It is not, therefore, my intention to treat the subject as it is treated in books on dietetics, but rather to indicate that the principles of dietetics branch naturally from the tree of knowledge and bear fruit which is, or may become, of great value. I shall endeavour to state some principles of dietetics and add a few words to each of them.

The first principle I would refer to is that the kind of food for which man is adapted is the same in all essentials as that on which he has subsisted for countless generations. This principle is lacking in direct practical utility, first, because we may not know exactly the kind of food on which primitive man and his ancestors did subsist; secondly, because we are not all agreed with regard to what are the essential elements of food; and thirdly, because man has introduced methods of preparation of foods which, though in some cases they may destroy or impair certain essential qualities, so far improve others that a reversion to primitive foods would be a retrograde step. The value of constantly bearing in mind this important principle, however, will be seen from some of the others which follow, for without this one a certain guide for the search for others would be lacking.

The next principle to which attention may be briefly directed is that the anatomy of the organs of digestion indicates the type of food which is most generally suitable for the animal under consideration. This has long been recognised by those who have concerned themselves with palæontological zoology. It has, however, been most completely disregarded by medical experts, who have occupied themselves with framing a pap dietary for young children which still too generally holds sway. It is now many years since the dental profession recognised that the complete temporary dentition indicated that the most suitable diet for a child was not pap, but should be of such a nature that the teeth and jaws would require to be used. Moreover, we recognised still further that the coming into position of the milk teeth indicated how the transition from the purely milk diet to the solid and varied diet suitable for children with a complete dentition should be brought about.

A correlated principle which we have to note is that the physiology of the organs of digestion indicates to some extent the type of food suitable for man. To begin with, however, what is the outstanding physiological process for which the first part of the alimentary canal is adapted? The incisor teeth incise or cut off portions of food, and the molars crush, tear, or physically disintegrate it, while at the same time the saliva and mucus are secreted. The muscles of mastication concerned with the closing of the mouth are physiologically adapted for the exercise of enormous pressure in order to disintegrate the food, while the muscles which open the mouth are relatively weak. If the food were intended to be swallowed without undergoing physical disintegration in the mouth there would be no need for the large muscles and elaborate physiological coördination which at present (necessarily) exist. As far as the digestion of food is concerned, the obvious inference is that with regard to the mouth and teeth the physical disintegration of the food is practically its one and only function, notwithstanding the fact that we may have books written on "The Work of the Digestive Glands" in which the salivary glands are largely referred to. Do not let us be befooled into believing that the physiological *raison d'être* of the salivary glands is solely or even primarily for the sake of digesting food. The salivary glands exist and function for the purpose of facilitating the movements of the mouth and food, for facilitating its disintegration, for facilitating deglutition, and for helping to clean it out of the mouth as rapidly as possible after the disintegration of the food is sufficiently advanced. We have heard a great deal about the digestion of starch by the ptyalin, and although the amount is very trivial it was well dinned into us that the function of the ptyalin was to digest starch (for nutritional purposes). Why a copious flow of saliva is poured out when sugar is taken into the mouth did not seem to suggest the idea that the function of the saliva was to clear substances out of the mouth which might be or become harmful to the teeth and mucous membranes during or after mastication. So again, we were taught that acid vegetable foods gave rise to a copious flow of alkaline saliva rich in ptyalin, but physiologists were silent with regard to the why of the ptyalin in this case. That the flow of alkaline saliva was to neutralise the acid was indicated, but that the saliva similarly became alkaline on eating meat was not mentioned and the rationale of such alkalinity was not indicated. So, too, we were led by physiologists to believe that the reason why ptyalin did not exist in the saliva of an infant till it had reached about the sixth month was that up to this age the child should not get starch in its dietary. No doubt an infant should not get starch in its dietary before this age, but why a ferment from the pancreas capable of digesting starch before this age existed was not told to us. The fact that the appearance of ptyalin in the saliva synchronised with the cutting of the teeth and that the saliva exists chiefly for the physiological cleanliness of the mouth and for the protection and preservation of the teeth was apparently never dreamt of. Although, then, the physiological reactions of the saliva to food show us clearly that they are adapted chiefly for facilitating disintegration of food and deglutition and to get rid of certain substances commonly associated with foods which are or might become injurious to the mouth and teeth, it would be a mistake to argue that whatsoever stimulates the salivary glands should necessarily be regarded as specially desirable food. Rather should we surmise that in foods which excite a great flow of saliva there may be an element of danger, if for any reason the glands were not capable of responding adequately to the stimulus, or if the food were of such a nature as to hamper the saliva in its attempt to get it out of the mouth. There is, then, an element of danger in food which contains sugar in greater proportion than it exists in vegetable foods as presented in nature, and the physiology of the glands of oral hygiene indicates that sweets, bread and jam, bread and marmalade, and the like should not be eaten at the end of or between meals.

I have not referred to mucus. Its function is largely that of lubrication, but it is also instrumental in maintaining the hygiene of the mouth, and when thoroughly incorporated with the food during mastication it no doubt facilitates the action of the gastric juice when the food reaches the stomach. Possibly this explains to some extent why, as Dr. Francis D. Boyd has ably shown, digestion is so very much better when the food requires mastication than when it is given in the form of pap.

Here it may be noted that the various principles of dietetics cannot be altogether isolated from one another, or perhaps we should say that various principles serve to reinforce each other, so it need hardly surprise us that our fourth principle has been adumbrated in what has already been said. This fourth principle is most important not only because of its practical application, but also because it has hitherto been completely overlooked by physiologists. I refer to the principle that the food should be of such a nature or the meal so arranged that the mouth and teeth will be left physiologically clean at the end of the meal. When once this principle is stated no one can deny it, for it is simply absurd to say that meals should leave the mouth in an unhygienic state. The wholesale destruction by caries of the teeth in civilised communities, together with the equally wholesale destruction of the gums and alveolar processes resulting from oral malhygiene, should have been sufficient to call attention to the importance of this principle, and except among those physiologists and medical men who consider that the mouth and teeth are outside their domain, the principle is now fairly recognised amongst the educated. Since the teeth of animals and primitive man are kept in a hygienic state by their foods, it is a simple guide to say that food in its natural condition will, if taken at the end of a meal, leave the mouth clean. For various reasons I have drawn attention to the value of uncooked fruit for this purpose, and need only add here that unless we are to revert to primitive foods and eschew all the benefits which accrue from the preparation and cooking of foods, we must above all other principles insist on this one.

Moreover, recognition that food should be of such a nature that the mouth and teeth should be left in a hygienic state leads by extension to the idea that the whole alimentary canal should be left in a similar hygienic state, and this suggests a still wider field for investigation. I have read that the alimentary canal of children nowadays is little more than a series of pathological specimens, and although this may be an exaggerated way of putting it, there is too much truth in the remark; and so long as the craze for nutrition and calorie values is considered to the exclusion of the hygienic value of food what truth there is in the observation will remain.

"Science knows no geographical boundaries," it only recognises the narrower limits of its own departments. Being under less than no obligation, however, to follow decadent scientific methods, we may be permitted to transgress the boundaries of our specialty and deal briefly with a few principles which have little or nothing to do with the mouth and teeth. They have, however, to do with the hygiene of the alimentary canal. As overeating is a common cause of alimentary malhygiene I shall deal with a few principles associated therewith. The first I shall mention is well known but seldom brought into force as it should be among the civilised. It is simply that "Hunger is the best sauce." Throughout the whole course of evolution our progenitors must often have been hungry, sometimes very, very hungry. If hunger had incapacitated them for food when it was found there would have been little chance for them surviving; fortunately it had quite the contrary effect. Pawlow has shown by approved experimental methods that digestion goes on best when associated with hunger, and in a general way we all know that it is so. Nevertheless I have practically never seen an emaciated child with an unhygienic digestive tract treated by keeping food away from it, and the unhygienic state of the alimentary canal is never given a chance of becoming hygienic.

This leads us to state another principle—namely, that tempting the palate habitually is contrary to the dictates of evolution. As the importance of economy in nutrition has throughout all ages only been transcended by the importance of getting enough we should recognise that a flagging appetite is a signal that amply sufficient has been consumed. We may be assured that as in past ages unlimited supplies of food were seldom available, as much as possible would be eaten of any food which contained the elements for supplying immediate needs and a reasonable reserve for the immediate future without special temptation. One might have thought that a scientist who recognised that hunger was the best sauce might also have recognised this principle. Nevertheless we read in Pawlow's work on the digestive glands: "The custom of the chief meal of the day also corresponds with our physiological results. After this or that *hors d'œuvre*, perhaps also with a liqueur of brandy (especially customary in Russia), both of which are designed to awaken the appetite, the repast proper begins, and, in the majority of cases, with something hot, consisting mostly of meat broth (*bouillon*, different soups, and so on). After this comes the really nourishing food—meat of different kinds served in various ways, or, in the case of poorer people, stews made with vegetables, and therefore rich in carbohydrate material. This sequence of foods, from the standpoint of physiology, is quite rational. Meat broth, as we have already seen, is an important chemical excitant of gastric secretion. An attempt is therefore made in two ways to secure a free secretion of gastric juice to act on the chief food: first, in the excitement of the appetite juice by the *hors d'œuvre*; and, secondly, in the promotion of the flow by the action of the meat broth." It would appear from this quotation and other similar statements that no effort either in the way of chemical or psychic excitant has to be spared to secure the activity of what seems to be presumed to be an otherwise insufficient organ for carrying on the work of digestion. Pawlow's ideas are interesting and instructive; unfortunately, however, they are not principles of dietetics: rather are they principles of gluttony. Much that is written about the arrangement of the meal from the glutton's point of view may be interpreted quite differently and more correctly. The meat or vegetable broth which so frequently commences a meal may have little or nothing to do with stimulating digestion; they may have chiefly to do with economy. A proportion of the available nutriment in yesterday's joint might be lost if the remains were not boiled and the resulting "stock" used on the following day. The words "stock" and "*pot au feu*" both suggest this interpretation. Pawlow follows what I have already quoted with the sentence: "The usual termination of the repast is also, from the physiological standpoint, easy to be understood. The chief meal is generally ended with something sweet, and everybody knows that sweets are pleasant. The meaning of this is easy to guess. The repast, begun with pleasure, consequent on the pressing need for food, must also, notwithstanding the stilling of hunger, be terminated with an agreeable sensation." Let us consider what is meant by "something sweet." Jam rolls, bread-and-honey, chocolate, &c., may all be recognised as something sweet or sweets, but yet, as it appears to me, his meaning in saying that the meal should be terminated by something sweet, yet which does not burden the work of the alimentary canal at this time, is not at all clear. It is quite obscure unless (which may be his meaning) we assume that sweet things do not burden digestion at this stage. But this would be quite erroneous. He refers also to acids, and attempts to show how acids one way and another assist digestion. He never appears to have dreamed that acids in foods were concerned with dental hygiene; in fact, the whole of his arguments indicate a conviction in the insufficiency of man's organs of digestion except when they are excited, whetted, and tempted by all sorts of psychic and chemical stimulant, and the philosophy of the correct termination of the meal is overlooked.

That the gustatory secretions should be stimulated at the end of a meal, not by sweets but by food of a natural, hygienic, or detergent nature, is evident to all who admit the principle that the mouth should be left physiologically clean. Now what does so most effectually? Fresh fruit certainly does; not only the dilute sugars but the acids, the aromatic and even the acrid substance in the fruit do so most effectually. Fruit contains but little nutriment, and its real value is hygienic and not nutritive—much less is it a digestive tonic. Foods in the form of sweets, jam rolls, bread and marmalade, chocolate, &c., are to be condemned absolutely as meal terminals, as their effect is the opposite of fruit, which leaves the mouth in a hygienic state. Read in the light of my theory I believe Pawlow's experiments are most instructive. Read in the darkness of the old craze for nutrition they are misleading, dangerous, and contradictory.

The amount of food eaten should not be regulated by principles of gluttony: it should be regulated indirectly by recognising the principles of dietetics. That the palate is a useful guide is not to be denied, and when it is given a chance to act it acts usefully. If the palate is given the opportunity to discover and appreciate the quality and quantity of the food which passes it, as when the food requires to be disintegrated and retained in the mouth for a time, then it will be a useful guide. If, on the other hand, food is given in the form of pap and is slipped past the palate without mastication, as it so often is in the feeding of young children, and geese which are being stuffed for *pâté de foie gras*, then the palate is but an imperfect guide both as regards quality and quantity. Nevertheless, let me say that instinct, custom, and common sense are not invariably to be relied upon. A new environment may come into existence relatively suddenly and the safeguards of necessary limitations existing in the aboriginal environment may disappear. Thus, for example, a relatively unlimited supply of carbohydrate foods may now be easily procured; in addition to this a gratuitous advocacy in influential quarters of the things most to be guarded against may usurp the place of natural limitations, as, for example, the advocacy of highly nutritious foods, the value of sugar as an economical foodstuff or as a proteid sparer, the advocacy of jam and marmalade instead of butter on bread, or the extolling of cocoa and chocolate instead of more hygienic and cheaper foods. It is for reasons such as these that we must have something more than instinct and custom. We need the principles of dietetics and a touch of common sense to be able to coördinate and make practical use of them.

With regard to a balanced dietary little need be said; the principles which regulate this too are similar to those which regulate the amount. Like the amount it is very variable, and if the organism, when restraints such as nature presents are imposed, is not fit to seek for and procure the balanced dietary required, no artificial endeavours will be likely to avail in the long run. The possibility of getting a fair choice and variety is of course necessary. Variety, however, should not simply be with regard to proteid, carbohydrate, fat, &c.; it should include also *uncooked* food. Fresh fruit, vegetables, and gustatory stimulants without regard to calories at all are necessary. Throughout the whole course of evolution uncooked food was consumed, and we certainly have not as yet sufficient evidence to make us disregard the probability that certain essential qualities are destroyed by cooking. Possibly the craze for having everything made easily digestible and sterilised before it enters the mouth accounts for much dyspepsia, and may explain why uncooked milk though full of germs, is such a useful drug in restoring what is sometimes necessary for healthy digestion.

I indicated above that restrictions on eating certain foods should be imposed to compensate for the lost restraints which nature imposed. If restraints in the nature of taxation for revenue on consuming alcohol, tea, and coffee are conducive to more good than evil, then surely the taxation of sugar, sweets, chocolate, and cocoa might for similar reasons be imposed, for, as Sir William Osler has maintained, decayed teeth are responsible for greater harm to the community than alcohol. Surely the proportion of misery which alcohol causes is not greater than the amount of dental troubles brought on by the eating of sweets. Indeed, Dr. Wheatley's statistics with regard to sweet-eating and caries clearly show this to be the case.

A further principle to which we may refer is that economy in diet is beneficial physically and morally. A long sermon might be preached on this subject; it is not, however, my intention to do so, firstly because it would be more instructive to hear how it is done from a housewife with a family, let us say, of five children and a husband with 30s. a week. Secondly, because it involves other considerations besides caloric or hygienic values. Thirdly, because the poor housewife in general does exceedingly well with the money at her disposal compared with those who usually give advice to this class. She does not require to be told that bread, oatmeal, and potatoes are economical compared with many other foods often belauded in medical journals, nor that cheap cuts of meat or cheap cheeses are of as high nutritive values as the more expensive kinds. All that I would say with regard to this principle is that to judge the value of a food by laboratory tests regarding its calorie value has been, and is, most misleading. A food such as uncooked fruit may have a high hygienic value. This may at times be wanted, but though it has calorie value is valueless when it is not wanted. Moreover, the judging of the cheapness of food by the amount of calories procurable from a given sum has led to advice which is worse than useless. Because an amount of sugar representing a large number of calories can be bought for a relatively small amount, it has been argued that sugar is an important and valuable food *for the poor*. Since, however, force of circumstances compels the poor to obtain the great bulk of their nourishment from bread or cereals and potatoes, and inasmuch as these contain relatively a superfluity of carbohydrates every penny spent on sugar by the poor is, from the point of view of nutrition, simply wasted. But this is not all. The sugar is often taken in a particularly obnoxious form, either as sweets between meals or as jam spread upon bread. Not only then is the money spent on the sugar wasted, but the fruit which is made into jam has most of its virtues destroyed as far as oral hygiene is concerned, and this at the considerable expense which is entailed in reducing it from the hygienic and palatable form in which nature provides it to the unhygienic form in which we see it prepared to destroy the teeth of the present day.

Another principle which should be considered by those who issue dietetic precepts is that functional activity is generally necessary for the most perfect development of an organ. A conspicuous illustration of this may be seen in the muscular development of the blacksmith's arm. This principle applies also with regard to the development of the salivary and probably also to other glands for the hygiene of the alimentary canal. Similarly without any doubt the muscular development of the organs of digestion is affected by the physical nature of the food. This is notably so in the case of the muscles of mastication; moreover, the development of the muscles of mastication has a distinct influence on the development of the jaws, and this again has its influence on the arrangement of the teeth. The anatomical perfection, then, of the first part at least of the digestive apparatus of man is quite appreciably affected by the physical nature of the food consumed in childhood.

I might refer to other principles which indicate, for example, that eating between meals should be avoided; that the concentration of the different elements composing foods (especially sugar) should not exceed the concentration habitually found in such foods as man throughout his evolution must have subsisted upon; that three meals a day are to be preferred to any greater number, &c.; but as these and other principles dealt with in this paper have been gone into in much greater detail in my books there is no need for further elaboration at present.

I should, in conclusion, like to refer to two reasons for bringing forward this communication. The first is to indicate that principles of dietetics might be formulated; and the second that the principles of dietetics or the value of foods cannot be established by those who set up laboratory tests and standards as criteria. Nor can they be deduced from the most elaborate statistics having reference to calorie values. The accumulation of statistics on nutritive values, however accurate, gives no more guide to hygienic values than do hygienic values give a guide to nutritive values, and the use of such statistics as a basis for generalising only prevents us from doing what science ought to do—namely, to methodise knowledge and reduce it to principles.

THE STERILISATION OF ALBUMINOUS CULTURE MEDIA BY ETHER.

BY PAUL FILDES, M.B., B.C. CANTAB.,
AND
L. W. RAJCHMAN, M.D.
(*From the Bacteriological Laboratory, London Hospital*—Professor WILLIAM BULLOCH, F.R.S.)

AT the present time, when many require sterile serum and ascitic fluid for the cultivation of certain bacteria, it may be opportune to publish a method for the sterilisation of such materials which we have utilised successfully.

When sterilised by heat, serum, and in particular horse serum, is apt to undergo changes which render it unsatisfactory for use. For instance, many samples of horse serum as obtained at a slaughter-house when heated to 60° C. become more or less completely "set," and thus cannot be mixed with other constituents in a culture medium. Further, the method of sterilisation by heat as applied to such fluids is far from being invariably successful in destroying contaminating bacteria.

Various volatile antiseptics, such as chloroform and toluol, have therefore been used for this purpose, but in our hands these additions have not always produced sterility, and, further, have the disadvantage of throwing down precipitates which take months to settle completely. On the other hand, ether as used by Ori[1] has been entirely satisfactory.

We have applied the method in the following way. 1. The serum or ascitic fluid is collected without any particular aseptic precautions and enclosed in a well-stoppered glass bottle. In the case of the ascitic fluid, which varies greatly in reaction, acid or alkali is added to render it neutral to phenolphthalein, and, if necessary, it is filtered through paper. 2. Ordinary methylated ether is added to 3 per cent. and the stopper tied in. 3. The bottle is then placed in a water-bath at 45° C. for one hour or longer to ensure that the serum is actually heated for the full time. 4. At the end of this time the fluid is found to be sterile and is stored for use. 5. When required a sample is removed from the bottle and placed in a sterile test-tube or other vessel. The test-tube is then thoroughly agitated in a water-bath at about 55° C.

---

[1] A. Ori: Biochemisches Centralblatt, 1906, v., 193.

and the ether will rapidly boil. When the ebullition has ceased the material will be ready for use. The ether will not boil unless the tube is shaken, and it must not be allowed to remain in the bath long enough for the serum to become thoroughly heated.

If the blood corpuscles have not been entirely separated from the serum before sterilisation they will be completely laked by the hot ether, and the resulting medium will be more or less deeply stained with hæmoglobin, but nevertheless quite transparent. No precipitation or cloudiness appears during the process; on the contrary, the fluids are rendered unusually clear. Within our experience this method has never failed to sterilise either ascitic fluid or serum.

Among the more obvious advantages of this procedure over any over, it will be noticed that the albumins are unchanged by heat, and thus the fluids are as efficient media as if they were collected aseptically from the living animal. The sterilisation is rapid and certain to such an extent that it is unnecessary to prove the sterility before use. Finally, the method is applicable to the preservation of certain immune sera; thus we have found that the activity of hæmolytic immune serum is not reduced by ether sterilisation.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A CASE OF TETANUS OCCURRING TEN WEEKS AFTER INJURY.

By ALEXANDER DON, F.R.C.S. EDIN.,
MAJOR, R.A.M.C. (T.F.), 1ST SCOTTISH GENERAL HOSPITAL, ABERDEEN.

A PRIVATE of the First Gordon Highlanders, aged 40 years, received a shrapnel wound on Dec. 21st, 1914; the bullet entered the right shoulder, fracturing the head of the humerus, the glenoid cavity, and the body of the scapula, and emerging opposite the inner scapular angle, 2 inches from the centre line. The wound was cleaned on admission on Dec. 31st. The scapula was much comminuted and several loose pieces were removed. Antitetanic serum was administered two days after the injury (Dec. 23rd) at Boulogne. On Jan. 28th, 1915, he was sent to Aboyne Auxiliary Hospital, and was re-admitted on March 2nd with symptoms of tetanus. The tetanus bacillus was discovered in the pus and in a piece of bone which extruded from the wound.

Three thousand units of serum were given the same night subcutaneously, also gr. xxx. potassium bromide and gr. x. chloral hydrate every four hours. Up to March 18th 147,000 units in all were given, doses varying from 3000 U.S. units a day to 20,000, according to the condition of the patient as regards frequency of spasms. It was noted that the severity of the spasms and of pain varied inversely as the number of units injected. On three occasions, March 4th, 5th, and 6th, he had 4000 units intravenously, by puncturing a dilated vein in the arm through the skin. On all these occasions a distinct red irritated area appeared within the next 24 hours.

Twice an attempt to give an intrathecal injection was made. At the first attempt no spinal fluid escaped, and the operation was abandoned. His back was very much curved by the opisthotonic spasms, but from daily experience of spinal anæsthesia I feel that I had reached the dural sac. On the 6th he was very bad, and a second intrathecal injection was attempted. Again no fluid escaped, but 2000 Lister Institute units were injected at high pressure, and the night following he became unconscious, passing fæces and urine in bed, and seemed moribund. He appeared to have cerebro-spinal meningitis, which was attributed to irritation from the serum. He recovered somewhat towards morning, and became conscious again shortly after.

For some days his condition was very critical, but by March 18th the spasms had entirely ceased, and no more serum was given. It seemed that the concentrated serum, supplied in 4000-unit ampoules, was irritating both intravenously and intrathecally. Also that the effect of the serum in controlling the spasms lasted for less than 24 hours, and modified the severity of the spasms in three or four hours after injection. A quarter of a grain of morphia controlled the pain and gave a more restful sleep than the chloral hydrate with the bromide. Morphia was not, however, given except during the night, and on instructions. Chloretone rectally in olive oil had no marked effect.

The patient all along took nourishment well. The wound was in no way red or inflamed. The spasms were most severe at first on the side of the injury and at the root of the neck.

The long period between the wound and the first symptoms of tetanus suggests either (*a*) a recent infection, or (*b*) a delay in the appearance of the disease, due to the prophylactic dose given at Boulogne. The pulse-rate reached 140 on March 5th and 6th at night, but the temperature was seldom above normal, and seemed to depend more on the amount of discharge from the wound than on the severity of the tetanic spasms. The patient is now progressing satisfactorily, but there is still some "position" rigidity, which is gradually wearing off.

COMA IN A CHILD.

BY J. H. DONNELL, M.B., B.C. CANTAB.,
CAPTAIN, R.A.M.C. (T.F.).

ON Saturday, May 16th, 1914, at 7 P.M., I was called to a case which presents some interesting speculations.

The patient was a boy, aged 8 years, residing in a neighbouring village. He was in a state of coma. The history obtained was that after running about a cricket-field on that rather warm afternoon, he had come in to tea, and during this meal, at 5.45 P.M., had suddenly become unconscious. There were no convulsions at the time, merely unconsciousness. When I saw him his limbs were flaccid, his pulse and colour good, the breathing was quiet, temperature 99° F., and the pupils were moderately dilated but reacted to light. I inquired from a brother who had been with him for the possibility of any herbal or other poisoning, but failed to elicit any information. Two drachms of castor oil in milk were slowly given by the mouth. At 8.45 P.M. convulsions set in and continued with but brief intervals till 10.15, when they became less frequent, the last occurring at about 11.30. He remained unconscious until 3 A.M. During this period the pulse and colour were good. The information was now elicited that some boys had said the lad had eaten some chestnut leaves. Later, after recovering consciousness, he vomited and there were some "green" red currants in the vomit. On questioning the boy on the morning of the 17th he confessed to having eaten unripe gooseberries and green red currants, but denied eating any chestnut leaves. He had never previously had convulsions in his life nor any epileptic fits, neither was there any history of similar conditions in the family. On this morning he complained of slight gastric pain, but otherwise he appeared well, and the castor oil had been effective.

The details of the above case suggest the question whether it really was a case of poisoning from the unripe fruit. I take it that in children convulsions are due not to an intoxication but to a gastro-intestinal irritation; also the patient was old for an infantile convulsion, and the sequence of coma first and convulsions later is not of the usual type. The sequence is equally wrong if an epileptic fit is suspected, and, as pointed out above, if it was an epileptic fit it was his first, and rather an unusual one in its characteristics.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Adeno-carcinoma (Mesothelioma) of the Kidney.—Congenital Cystic Kidneys.

A MEETING of this section was held on May 7th, Professor E. J. McWEENEY being in the chair.

Mr. T. T. O'FARRELL read a paper on a specimen of Adeno-carcinoma (Mesothelioma) of the Kidney. The specimen was a tumour of the left kidney removed by operation by Dr. M. C. Staunton, to whom Mr. O'Farrell tendered his thanks for leave to exhibit the specimen. The patient was a girl aged 6 years. Since she had been two years old she suffered from vague abdominal uneasiness and for the past two years the abdomen had been noticeably distended. There were no marked symptoms apart from occasional attacks of pain; there had been no wasting, hæmaturia, or evidence of any secondary deposits. Since operation the child appeared much improved and at the present time is running about apparently in the best of health. To the naked eye the kidney was uniformly enlarged, showing some prominences in places; the tumour seemed continuous with the organ, but in part, more particularly towards the pelvis, the kidney substance was flattened out and formed a shell about the tumour. The specimen measured 15 by 9 by 7 cm. On section the tumour was soft and divided into distinct lobules, which varied in size from 8 cm. to 0·5 cm. in diameter. The greater bulk of the tumour was towards one pole, but the kidney substance was almost everywhere infiltrated by the growth. Microscopically sections taken from different parts showed typical adeno-carcinoma, with regular and irregular acini. After careful examination no other neoplastic cellular element, such as sarcoma, could be found. The naked-eye appearances of the specimen exhibited, taken with the youth of the patient, were strongly in favour of a diagnosis of teratoblastoma, a not uncommon kidney tumour of children. But though he kept in mind that in these tumours one element—the carcinomatous one—may preponderate, the specimen exhibited could not be regarded as such, for not even a trace of other element than the carcinomatous one could be found, and hence he thought it should properly be called a true blastoma, a tumour arising from unpotential cells, in this case a mesothelioma, and accordingly an extremely rare one in such a young patient.

Professor McWEENEY said that after examining Mr. O'Farrell's microscopical specimens he had no doubt that, apart from embryological considerations, the tumour should be called an adeno-carcinoma.

Professor H. METTAM said he did not see why a new growth in the kidney should not be of a compound papillomatous nature, such as is met with in the ovary.

Mr. O'FARRELL, in replying, said he was pleased to have had his diagnosis confirmed as to the adeno-carcinomatous appearance of the specimen. The presence of muscle fibres was, he thought, a not uncommon finding in kidney tumours, and was probably due to inclusions from the sclerotome.

Professor McWEENEY exhibited the Kidneys of a male, aged 47 years, who died at the Mater Misericordiæ Hospital in a uræmic seizure. The patient was alcoholic, but had enjoyed good health until three weeks prior to admission, when he began to suffer from "fits." He complained of headache, tenderness over the left hypogastrium, violent pains in the calves of his legs, and diarrhœa. The seizures consisted of clonic spasms lasting about 15 minutes, giving place to coma, with stertorous breathing, which lasted about three hours. The pupils were unequal and knee-jerks absent. After a seizure the patient was quite collected and intelligent. On palpation a large tumour could be felt in the left hypochondrium. The patient only lived two and a half days after admission. Shortly before his death a white frost-like efflorescence was noticed on the skin of the face. The urine had a specific gravity of 1010, and contained a small amount of albumin. Samples were difficult to obtain, and it was not fully examined. At the necropsy the left kidney measured 20 by 10 by 10 cm. and weighed 1250 grammes. The right measured 17 by 10 by 8 cm. and weighed 850 grammes. The pelves and ureters were remarkably small. The kidney substance was reduced to small patches of parenchyma wedged in between innumerable cysts, and there was no distinction between cortex and medulla. The cysts were of all sizes up to that of a walnut, and the contents of some were thinly liquid, whilst others contained solid translucent brownish material like inspissated glue. Some of the cysts contained minute yellow spherical concretions with laminated and radiated structure, and consisting of an albuminous matrix with lime salts—chiefly carbonate. The largest seen measured 0·3 mm. in diameter. Microscopically very few glomeruli were visible, and of these the majority were hyaline, with a laminated Bowman's capsule. The cysts were lined with a single line of cubical epithelium, tending to disappear in the larger ones. The connective tissue was much increased and contained patches of lymphoid cells and unstriped muscle. There were patches of cells of epithelial aspect lying free in the connective tissue and suggestive of carcinoma, but presenting no evidence of mitotic activity.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the West London Hospital on June 4th, Colonel T. H. Hendley, I.M.S., being in the chair.—Dr. F. S. Palmer read a paper on the Functional Palsies and their Recognition, in the course of which he said that excluding cancer and tuberculosis there were few terms more awe-inspiring and loosely applied than that of paralysis. To the lay mind its significance was serious and unmistakable, and the popular view was probably based on the results seen in organic cases alone. The recognition of the functional examples was of paramount importance to the clinician. No distinction could be drawn between the words hysterical and functional as applied to paralysis. Organic disease and functional disorders might co-exist, as sometimes seen in cases of cerebral tumour. Many grave diseases of the nervous system developed on functional lines and for a time masked the underlying cause, especially the irregular forms of disseminated sclerosis; in their earlier stages they were sometimes indistinguishable. The diagnosis of the functional palsies was made by the exclusion of organic signs, evidence supplied by the examination of reflexes, and the recognition of hysterical personality. Ordinarily recovery was the rule except in long-standing cases with fibrotic changes in the joint and tendons. Sensation might or might not be disturbed, but usually marked anæsthesia in some form was present. Although it was often profound, and frequently changed its position, it never corresponded to the anatomical distribution of the paralysis, which varied from slight motor weakness to absolute loss of power. Within recent years some special signs had been noted of great diagnostic value to practitioners. Besides several local palsies the types usually encountered were monoplegia, hemiplegia, and paraplegia; diplegia and quadriplegia were so rarely seen that they did not require attention. Much importance was attached to the study of the reflexes, especially the plantar response, gait, pupillary and electrical reactions, together with the use of the ophthalmoscope. Of the local palsies hysterical aphonia due to paralysis of the adductors, in the eye concentric contraction of the visual fields, and in the ocular region pseudo-ptosis from spasm of the orbicular muscle were the most common. Some of the functional palsies were comparatively easy to recognise, but others were problems of great difficulty.—Mr. N. Bishop Harman, Dr. Alastair MacGregor, Dr. A. Ogier Ward, Mr. O. L. Addison, and others took part in the subsequent discussion, to which Dr. Palmer replied.

Reviews and Notices of Books.

Œdema and Nephritis: A Critical, Experimental, and Clinical Study of the Physiology and Pathology of Water Absorption in the Living Organism.

By MARTIN H. FISCHER, M.D., Eichberg Professor of Physiology in the University of Cincinnati. Second edition, revised and enlarged. With 160 figures. London: Chapman and Hall; New York: J. Wiley and Sons. 1915. Pp. x.-696. Price 21*s.* net.

DURING the last eight years Dr. Fischer has written extensively on the subjects treated of in this volume, which is an elaboration of the two volumes on "Œdema" and on "Nephritis" that formed its first edition. To sum up its contents in a single phrase, it may be described as an apotheosis of colloid chemistry in explaining the physiology and pathology of living matter.
